1. FEATURES

- 1G-bit SLC NAND Flash
  - Bus: x8, x16
  - Page size: (2048+64) byte for x8 bus, (1024+32) word for x16 bus
  - Block size: (128K+4K) byte for x8 bus, (64K+2K) word for x16 bus
  - Plane size: 1024-block/plane x 1
- **ONFI 1.0 compliant**
- **Multiplexed Command/Address/Data**
- **User Redundancy**
  - 64-byte attached to each page
- **Fast Read Access**
  - Latency of array to register: 25us
  - Sequential read: 25ns
- **Cache Read Support**
- **Page Program Operation**
  - Page program time: 320us (typ.)
- **Cache Program Support**
- **Block Erase Operation**
  - Block erase time: 1ms (typ.)
- **Single Voltage Operation:**
  - VCC: 1.7 ~ 1.95V
- **Low Power Dissipation**
  - Max. 30mA (1.8V) Active current (Read/Program/Erase)
- **Sleep Mode**
  - 50uA (Max) standby current
- **Hardware Data Protection:** WP# pin
- **Device Status Indicators**
  - Ready/Busy (R/B#) pin
  - Status Register
- **Chip Enable Don't Care**
  - Simplify System Interface
- **Unique ID Read support (ONFI)**
- **Secure OTP support**
- **Electronic Signature (5 Cycles)**
- **High Reliability**
  - Endurance: typical 100K cycles (with 4-bit ECC per (512+16) Byte)
  - Data Retention: 10 years
- **Wide Temperature Operating Range**
  - -40°C to +85°C
- **Package:**
  - 1) 48-TSOP(I) (12mm x 20mm)
  - 2) 63-ball 9mmx11mm VFBGA
  - 3) 48-ball 6mmx8mm VFBGA

  All packaged devices are RoHS Compliant and Halogen-free.

2. GENERAL DESCRIPTIONS

The MX30UF1G16(18)AC is a 1Gb SLC NAND Flash memory devices. Its standard NAND Flash features and reliable quality of typical P/E cycles 100K (with ECC), which make it most suitable for embedded system code and data storage.

The product family requires 4-bit ECC per 528B.

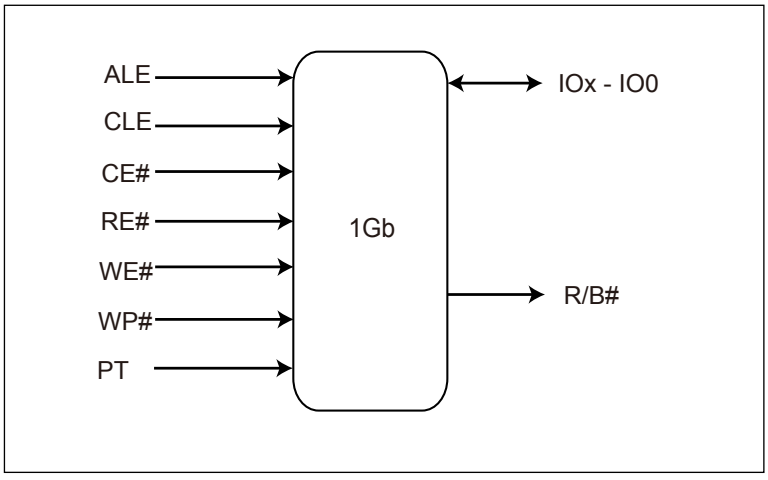

This device is typically accessed in pages of 2,112 bytes (x8) or 1,056 words (x16), both for read and for program operations.

The device's array is organized as thousands of blocks, which is composed by 64 pages of (1,024+32) words in one single NAND strings structure with 32 serial connected cells in each string. Each page has an additional 32 words for ECC and other purposes. The device has an on-chip buffer of 2,112 bytes or 1,056 words (x16) for data load and access.

The Cache Read Operation of the MX30UF1G16(18)AC enables first-byte read-access latency of 25us and sequential read of 25ns and the latency time of next sequential page will be shorten from tR to tRCBSY.

The MX30UF1G16(18)AC power consumption is 30mA during all modes of operations (Read/Program/Erase), and 50uA in standby mode.

3-1. PIN DESCRIPTIONS

SYMBOL	PIN NAME
IOx - IO0	Data I/O port: IO7-IO0 for x8 device, IO15-IO0 for x16 device
CE#	Chip Enable (Active Low)
RE#	Read Enable (Active Low)
WE#	Write Enable (Active Low)
CLE	Command Latch Enable
ALE	Address Latch Enable
WP#	Write Protect (Active Low)
R/B#	Ready/Busy (Open Drain)
PT	Protection (Active High) for entire chip protection. A weak pull-down internally
VSS	Ground
VCC	Power Supply for Device Operation
NC	Not Connected Internally

PIN FUNCTIONS

The MX30UF1G16(18)AC device is a sequential access memory that utilizes multiplexing input of Command/Address/Data.

I/O PORT: IOx - IO0

The IOx to IO0 pins are for address/command input and data output to/from the device. IO7-IO0 pins are for x8 device, IO15-IO0 pins are for x16 device.

CHIP ENABLE: CE#

The device goes into low-power Standby Mode when CE# goes high during a read operation and not at busy stage.

The CE# goes low to enable the device to be ready for standard operation. When the CE# goes high, the device is deselected. However, when the device is at busy stage, the device will not go to standby mode when CE# pin goes high.

READ ENABLE: RE#

The RE# (Read Enable) allows the data to be output by a tREA time after the falling edge of RE#. The internal address counter is automatically increased by one at the falling edge of RE#.

WRITE ENABLE: WE#

When the WE# goes low, the address/data/command are latched at the rising edge of WE#.

COMMAND LATCH ENABLE: CLE

The CLE controls the command input. When the CLE goes high, the command data is latched at the rising edge of the WE#.

ADDRESS LATCH ENABLE: ALE

The ALE controls the address input. When the ALE goes high, the address is latched at the rising edge of WE#.

WRITE PROTECT: WP#

The WP# signal keeps low and then the memory will not accept the program/erase operation. It is recommended to keep WP# pin low during power on/off sequence. Please refer to the waveform of "Power On/Off Sequence".

READY/Busy: R/B#

The R/B# is an open-drain output pin. The R/B# outputs the ready/busy status of read/program/erase operation of the device. When the R/B# is at low, the device is busy for read or program or erase operation. When the R/B# is at high, the read/program/erase operation is finished.

Please refer to **Section 9-1** for details.

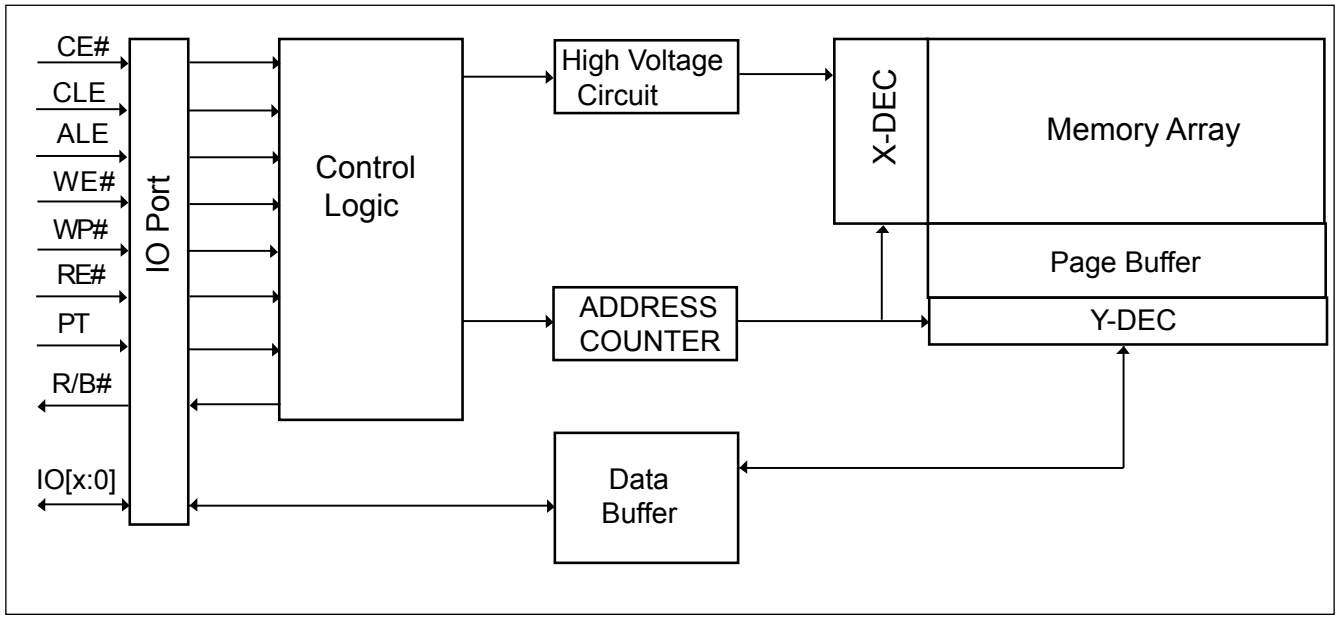

PROTECTION: PT

The PT pin is the hardware method to protect the whole chip from program/erase operation. When the PT pin is at high at power-on, the whole chip is protected even the WP# is at high; the un-protect command and procedure is necessary before any program/erase operation. When the PT pin is connected to low or floating, the Protection function is disabled.

Please refer to **Section - Block Protection** for details.

5. SCHEMATIC CELL LAYOUT AND ADDRESS ASSIGNMENT

The device is a 1Gb single plane device, which is composed by 64 pages of (2,048+64)-byte in two NAND strings structure with 32 serial connected cells in each string. Each page has an additional 64 bytes for ECC and other purposes. The device has an on-chip buffer of 2,112 bytes for data load and access. Each 2K-Byte page has the two area, one is the main area which is 2048-bytes and the other is spare area which is 64-byte.

There are four address cycles for the address allocation, please refer to the lable below.

Table 1-1. Address Allocation (for x8): MX30UF1G18AC

Addresses	IO7	IO6	IO5	IO4	IO3	IO2	IO1	IO0
Column address - 1st cycle	A7	A6	A5	A4	A3	A2	A1	A0
Column address - 2nd cycle	L	L	L	L	A11	A10	A9	A8
Row address - 3rd cycle	A19	A18	A17	A16	A15	A14	A13	A12
Row address - 4th cycle	A27	A26	A25	A24	A23	A22	A21	A20

Table 1-2. Address Allocation (for x16): MX30UF1G16AC

Addresses	IO15-IO8	IO7	IO6	IO5	IO4	IO3	IO2	IO1	IO0
Column address - 1st cycle	L	A7	A6	A5	A4	A3	A2	A1	A0
Column address - 2nd cycle	L	L	L	L	L	L	A10	A9	A8
Row address - 3rd cycle	L	A18	A17	A16	A15	A14	A13	A12	A11
Row address - 4th cycle	L	A26	A25	A24	A23	A22	A21	A20	A19

6. DEVICE OPERATIONS

6-1. Address Input/Command Input/Data Input

Address input bus operation is for address input to select the memory address. The command input bus operation is for giving command to the memory. The data input bus is for data input to the memory device.

6-2. Page Read

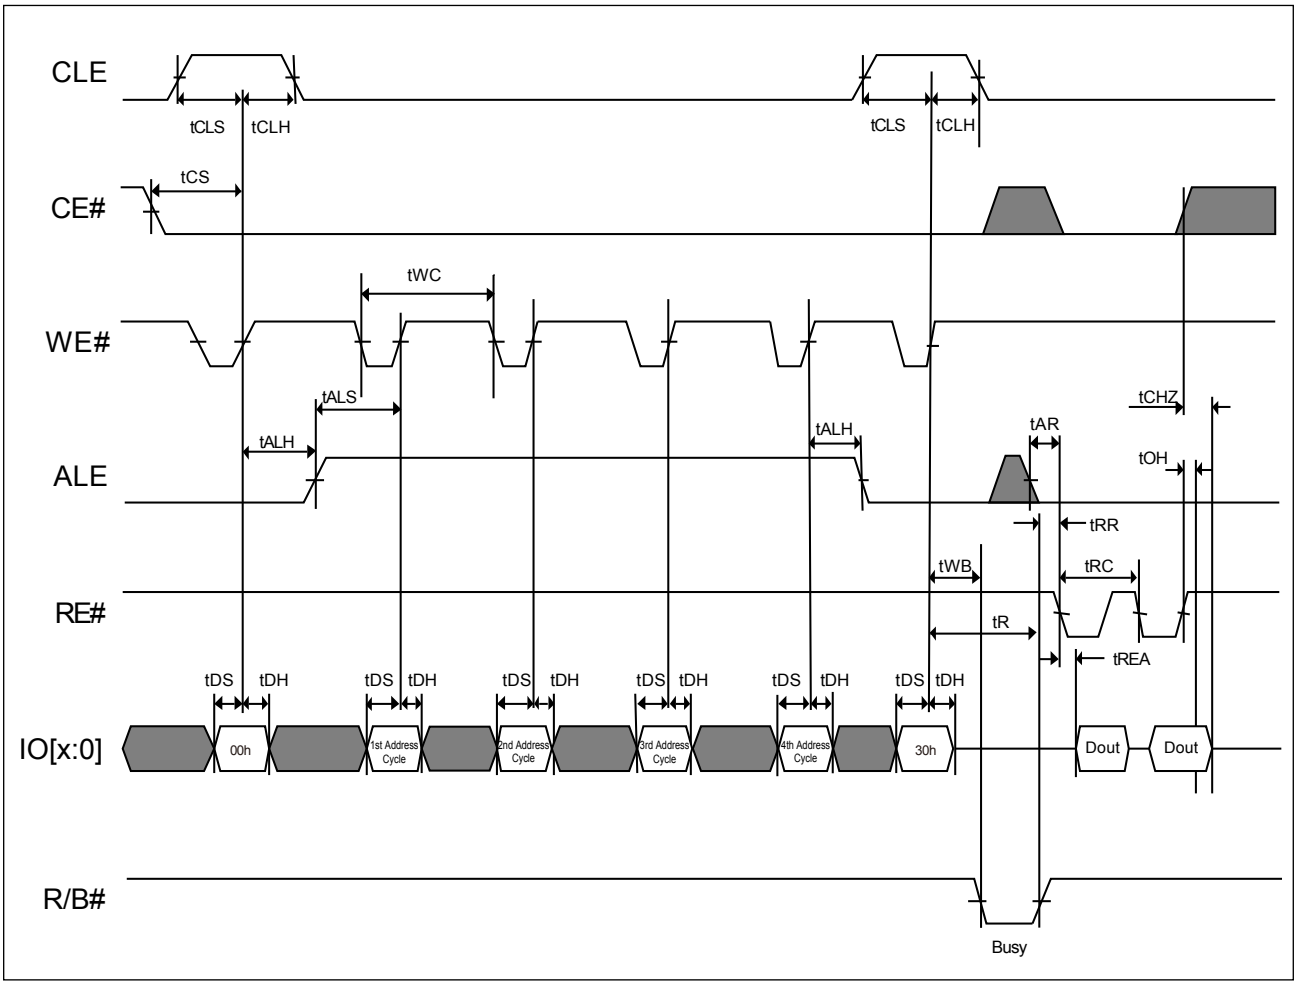

The MX30UF1G16(18)AC array is accessed in Page of 2,112 bytes or 1,056 words. External reads begins after the R/B# pin goes to READY.

The Read operation may also be initiated by writing the 00h command and giving the address (column and row address) and being confirmed by the 30h command, the device begins the internal read operation and the chip enters busy state. The data can be read out in sequence after the chip is ready. Refer to the waveform for Read Operation as below.

If the host side uses a sequential access time (tRC) of less than 30ns, the data can be latched on the next falling edge of RE# as the waveform of EDO mode (**Figure 9-2**).

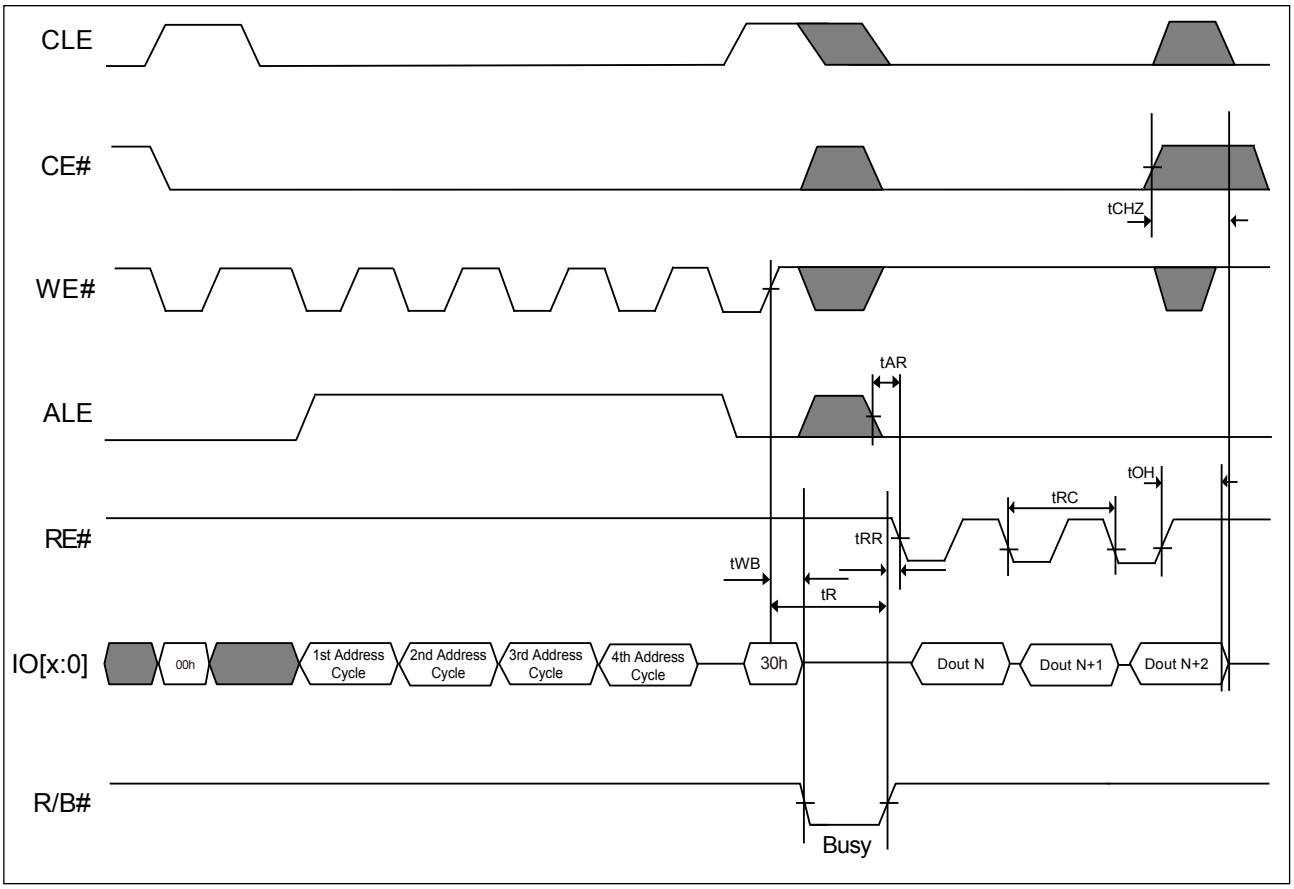

To access the data in the same page randomly, a command of 05h may be written and only column address following and then confirmed by E0h command.

深圳市满度科技有限公司
Web:www.manduic.com
Tel:150-1290-5940
Email:sales@manduic.com
Downloaded from Arrow.com.

6-3. Cache Read Sequential

The cache read sequential operation is for throughput enhancement by using the internal cache buffer. It allows the consecutive pages to be read-out without giving next page address, which reduces the latency time from tR to tRCBSY between pages or blocks. While the data is read out on one page, the data of next page can be read into the cache buffer.

After writing the 00h command, the column and row address should be given for the start page selection, and followed by the 30h command for address confirmation. After that, the CACHE READ operation starts after a latency time tR and following a 31h command with the latency time of tRCBSY, the data can be read-out sequentially from 1st column address (A[11:0]=000h for x8; A[10:0]=000h for x16) without giving next page address input. The 31h command is necessary to confirm the next cache read sequential operation and followed by a tRCBSY latency time before next page data is necessary. The CACHE READ SEQUENTIAL command is also valid for the consecutive page cross block.

The random data out (05h-E0h) command set is available to change the column address of the current page data in the cache register.

The user can check the chip status by the following method:

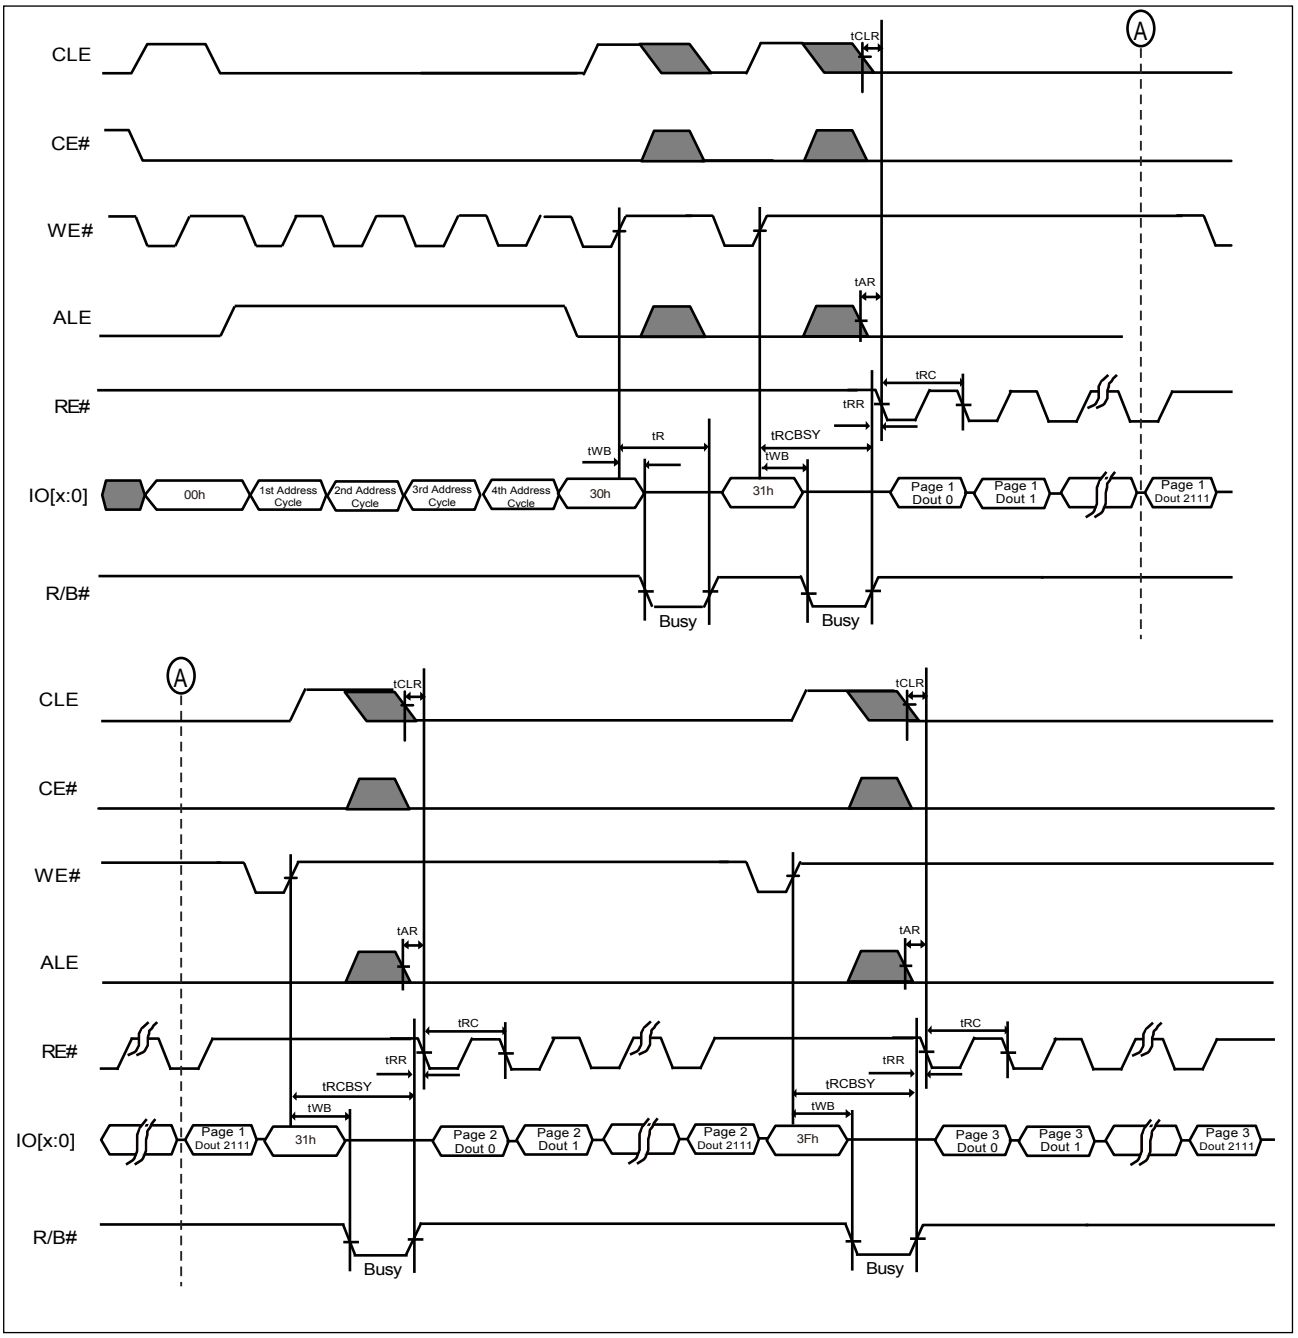

- R/B# pin ("0" means the data is not ready, "1" means the user can read the data)

- Status Register (SR[6] functions the same as R/B# pin, SR[5] indicates the internal chip operation, "0" means the chip is in internal operation and "1" means the chip is idle.) Status Register can be checked after the Read Status command (70h) is issued. Command 00h should be given to return to the cache read sequential operation.

To confirm the last page to be read-out during the cache read sequential operation, a 3Fh command is needed to replace the 31h command prior to the last data-out.

深圳市满度科技有限公司
Web:www.manduic.com
Tel:150-1290-5940
Email:sales@manduic.com
Downloaded from Arrow.com.

6-4. Cache Read Random

The main difference from the Cache Read Sequential operation is the Cache Read Random operation may allow the random page to be read-out with cache operation not just for the consecutive page only.

After writing the 00h command, the column and row address should be given for the start page selection, and followed by the 30h command for address confirmation. The column address is ignored in the cache read random operation. And then, the CACHE READ RANDOM operation starts after a latency time tR and following a 00h command with the selected page address and following a 31h command, the data can be read-out sequentially from 1st column address (A[11:0]=000h for x8; A[10:0]=000h for x16) after the latency time of tRCBSY. After the previous selected page data out, a new selected page address can be given by writing the 00h-31h command set again. The CACHE READ RANDOM command is also valid for the consecutive page cross block.

The random data out (05h-E0h) command set is available to change the column address of the current page data in the cache register.

The user can check the chip status by the following method:

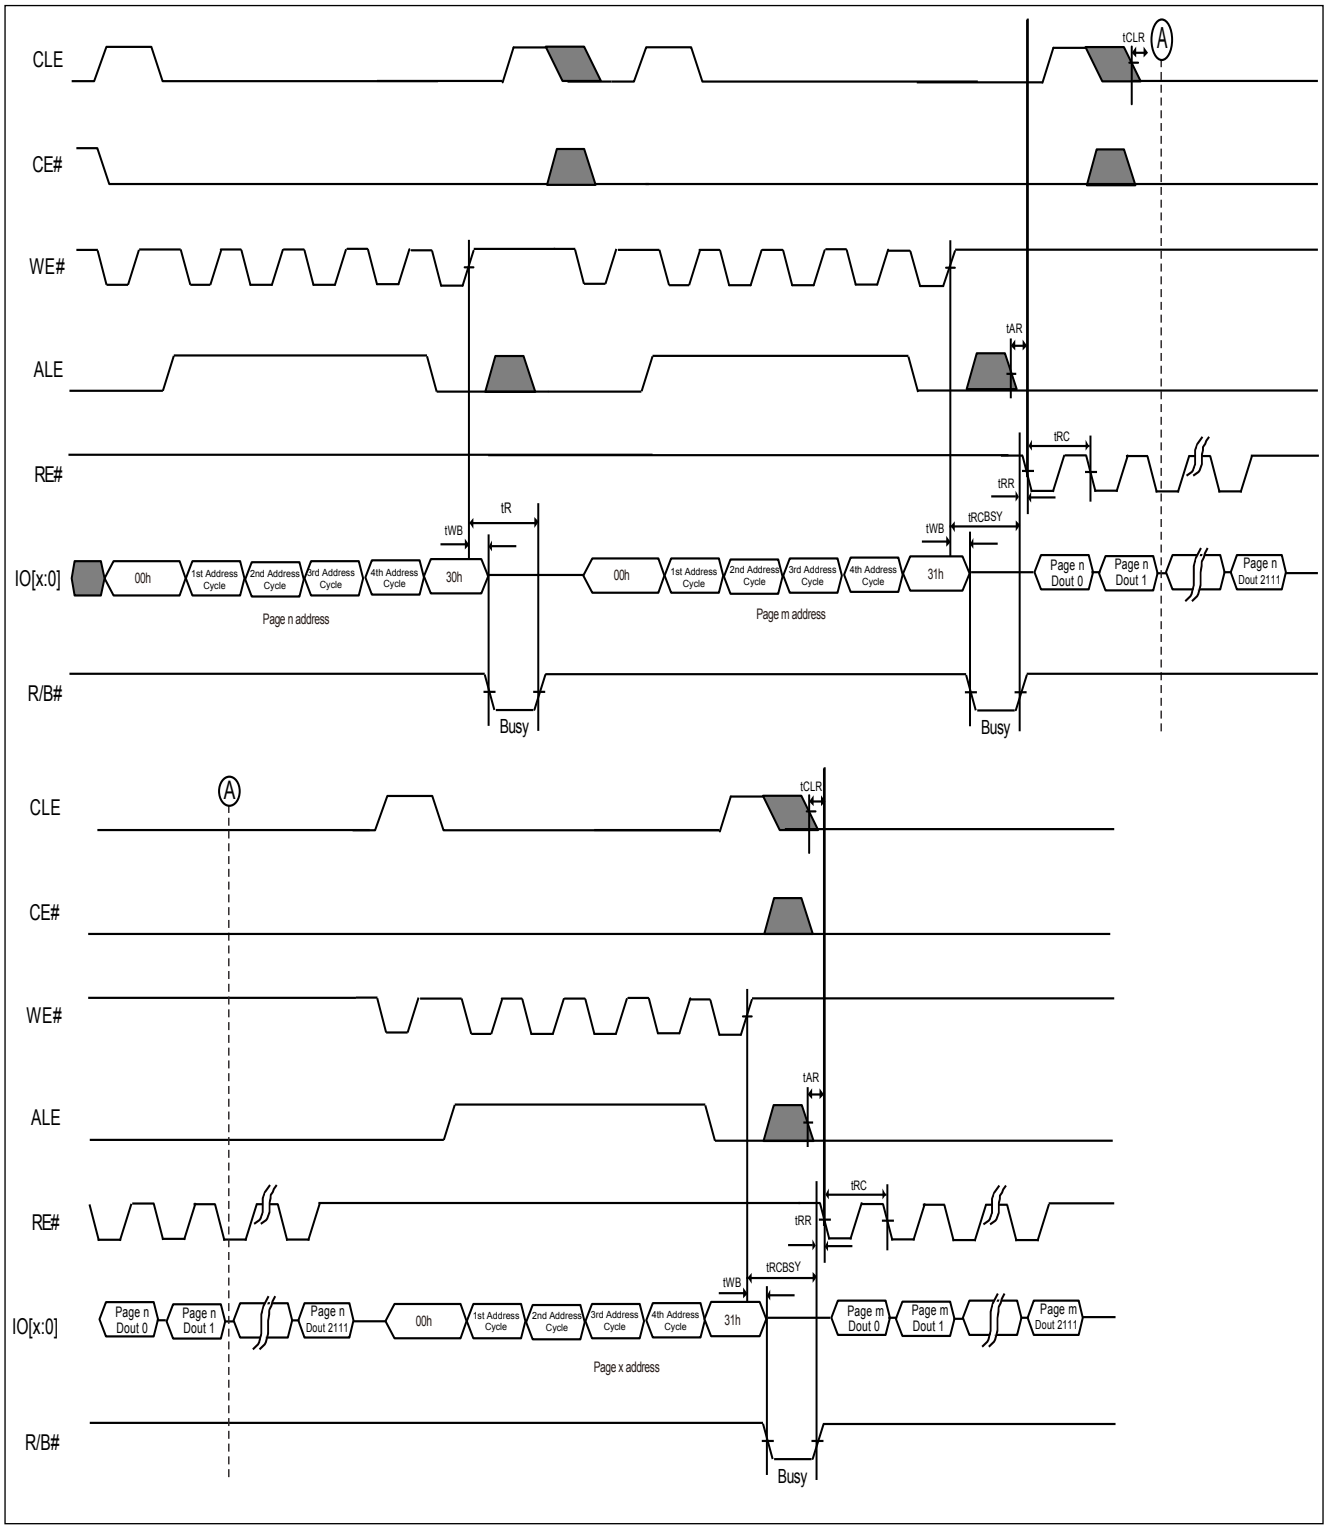

- R/B# pin ("0" means the data is not ready, "1" means the user can read the data)

- Status Register can be checked after the Read Status command (70h) is issued. (SR[6] behaves the same as R/B# pin, SR[5] indicates the internal chip operation, "0" means the chip is in internal operation and "1" means the chip is idle.) Command 00h should be given to return to the cache read operation.

To confirm the last page to be read-out during the cache read operation, a 3Fh command is needed to replace the 31h command prior to the last data-out.

6-5. Page Program

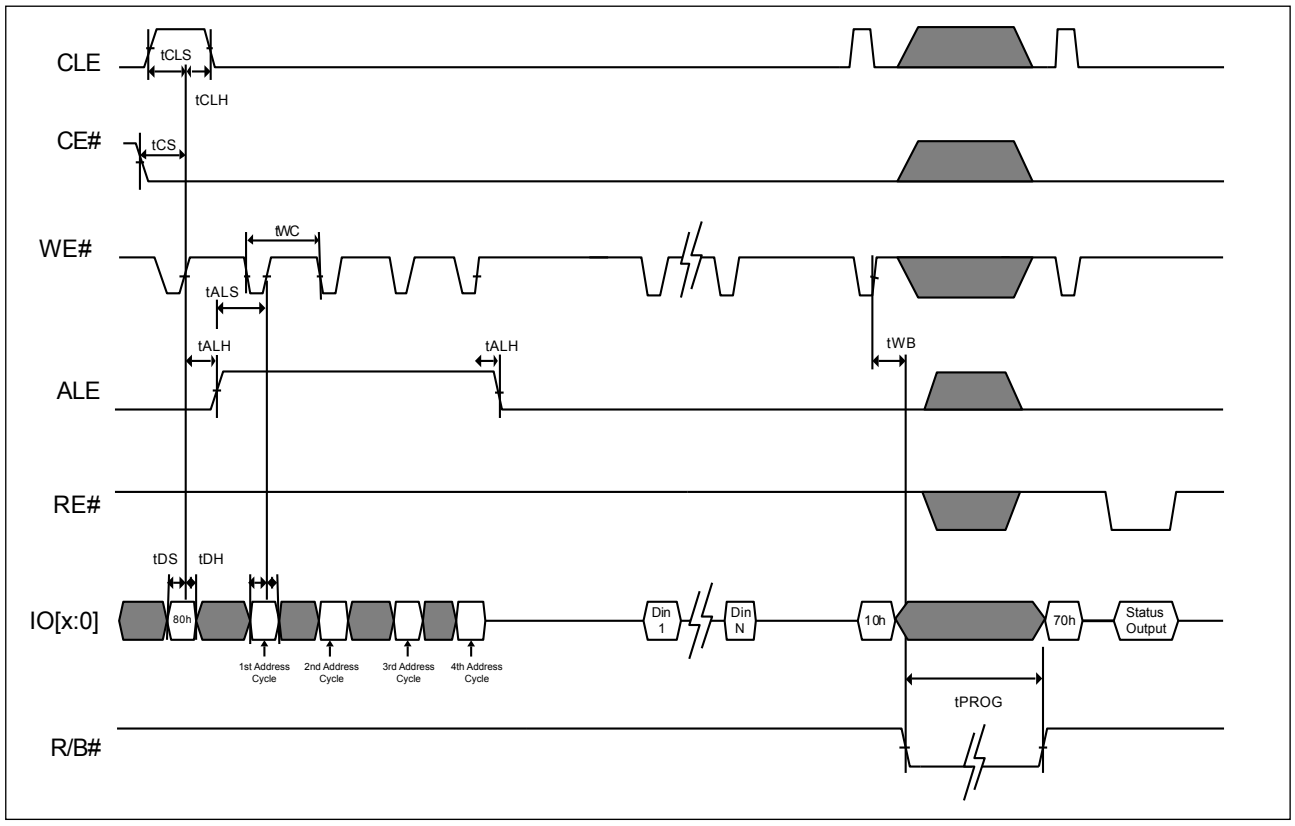

The memory is programmed by page, which is 2,112 bytes, or 1056 words. After Program load command (80h) is issued and the row and column address is given, the data will be loaded into the chip sequentially. Random Data Input command (85h) allows multi-data load in non-sequential address. After data load is complete, program confirm command (10h) is issued to start the page program operation. The page program operation in a block should start from the low address to high address. Partial program in a page is allowed up to 4 times. However, the random data input mode for programming a page is allowed and number of times is not limited.

The status of the program completion can be detected by R/B# pin or Status register bit SR[6].

The program result is shown in the chip status bit (SR[0]). SR[0] = 1 indicates the Page Program is not successful and SR[0] = 0 means the program operation is successful.

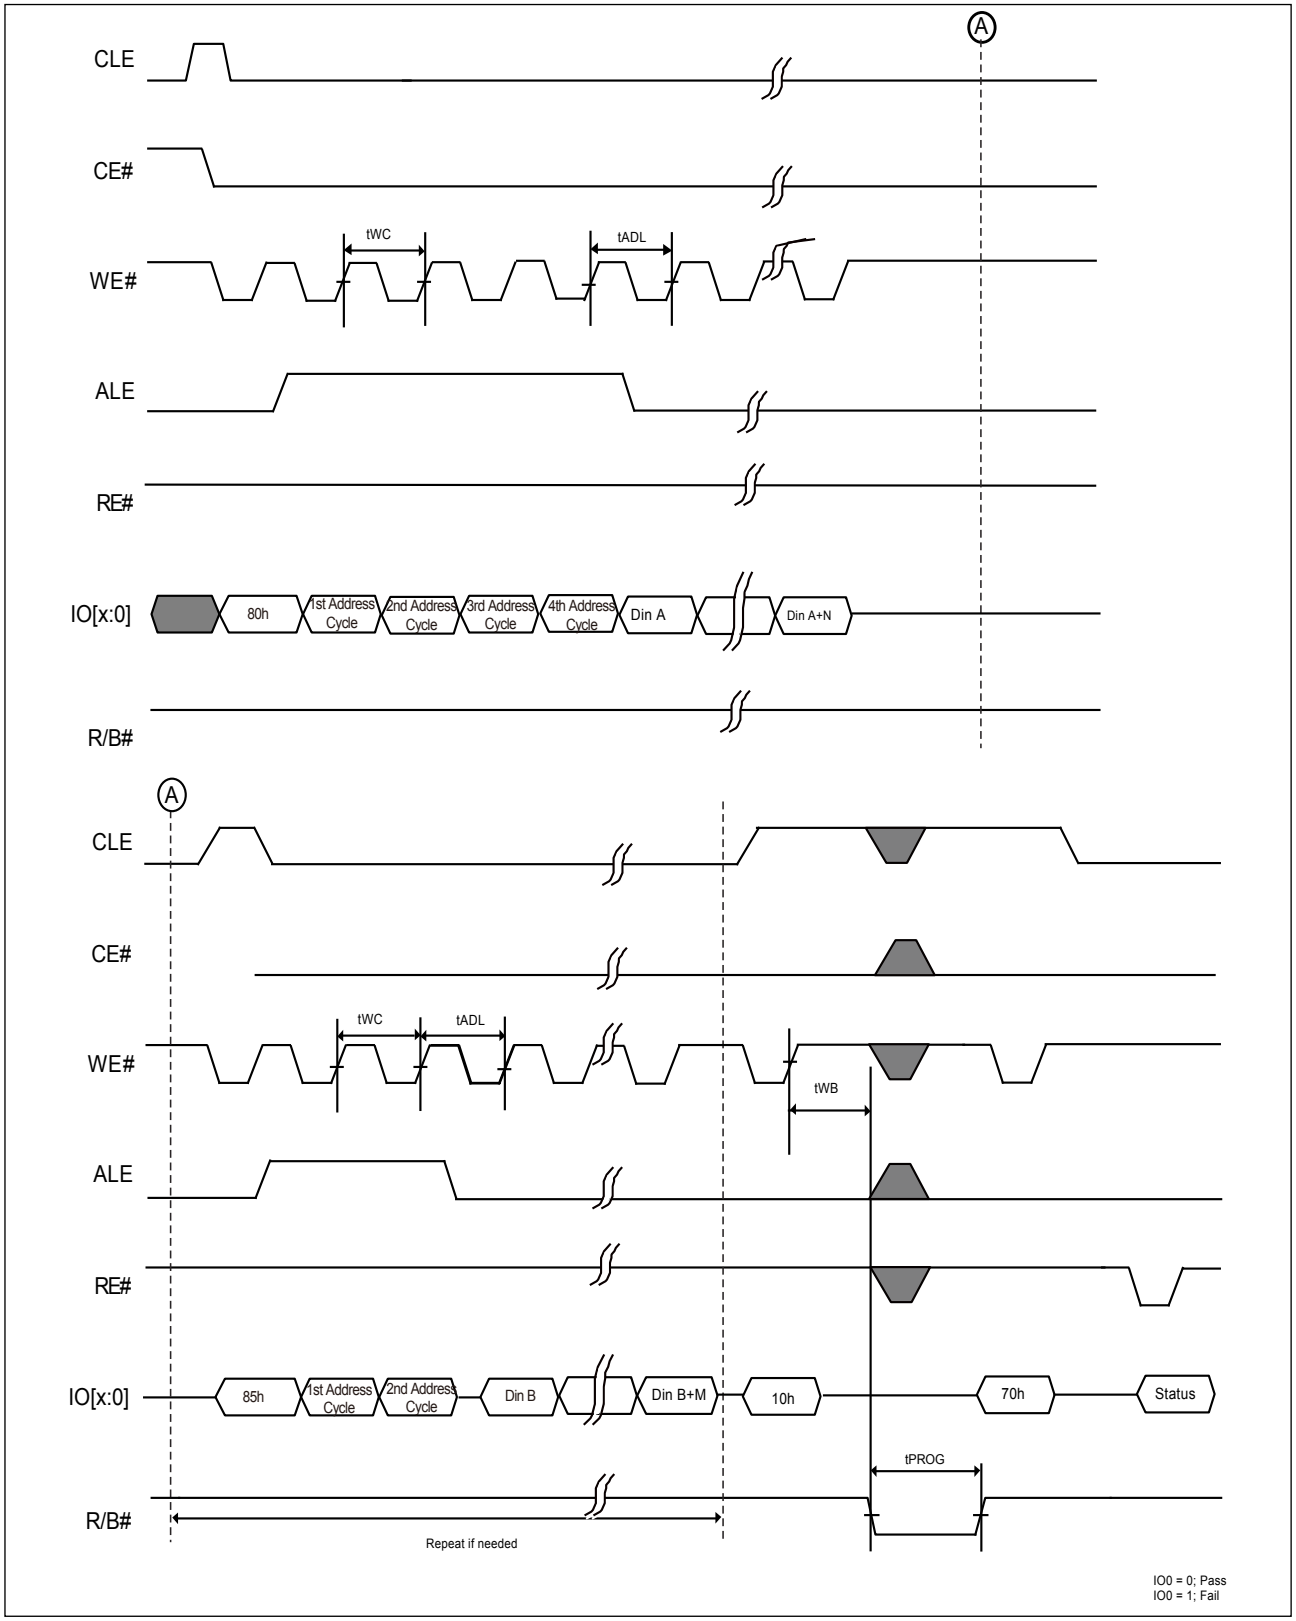

During the Page Program progressing, only the read status register command and reset command are accepted, others are ignored.

6-6. Cache Program

The cache program feature enhances the program performance by using the cache buffer of 2,112-byte or 1,056 words. The serial data can be input to the cache buffer while the previous data stored in the buffer are programming into the memory cell. Cache Program command sequence is almost the same as page program command sequence. Only the Program Confirm command (10h) is replaced by cache Program command (15h).

After the Cache Program command (15h) is issued. The user can check the status by the following methods.

- R/B# pin

- Cache Status Bit (SR[6] = 0 indicates the cache is busy; SR[6] = 1 means the cache is ready).

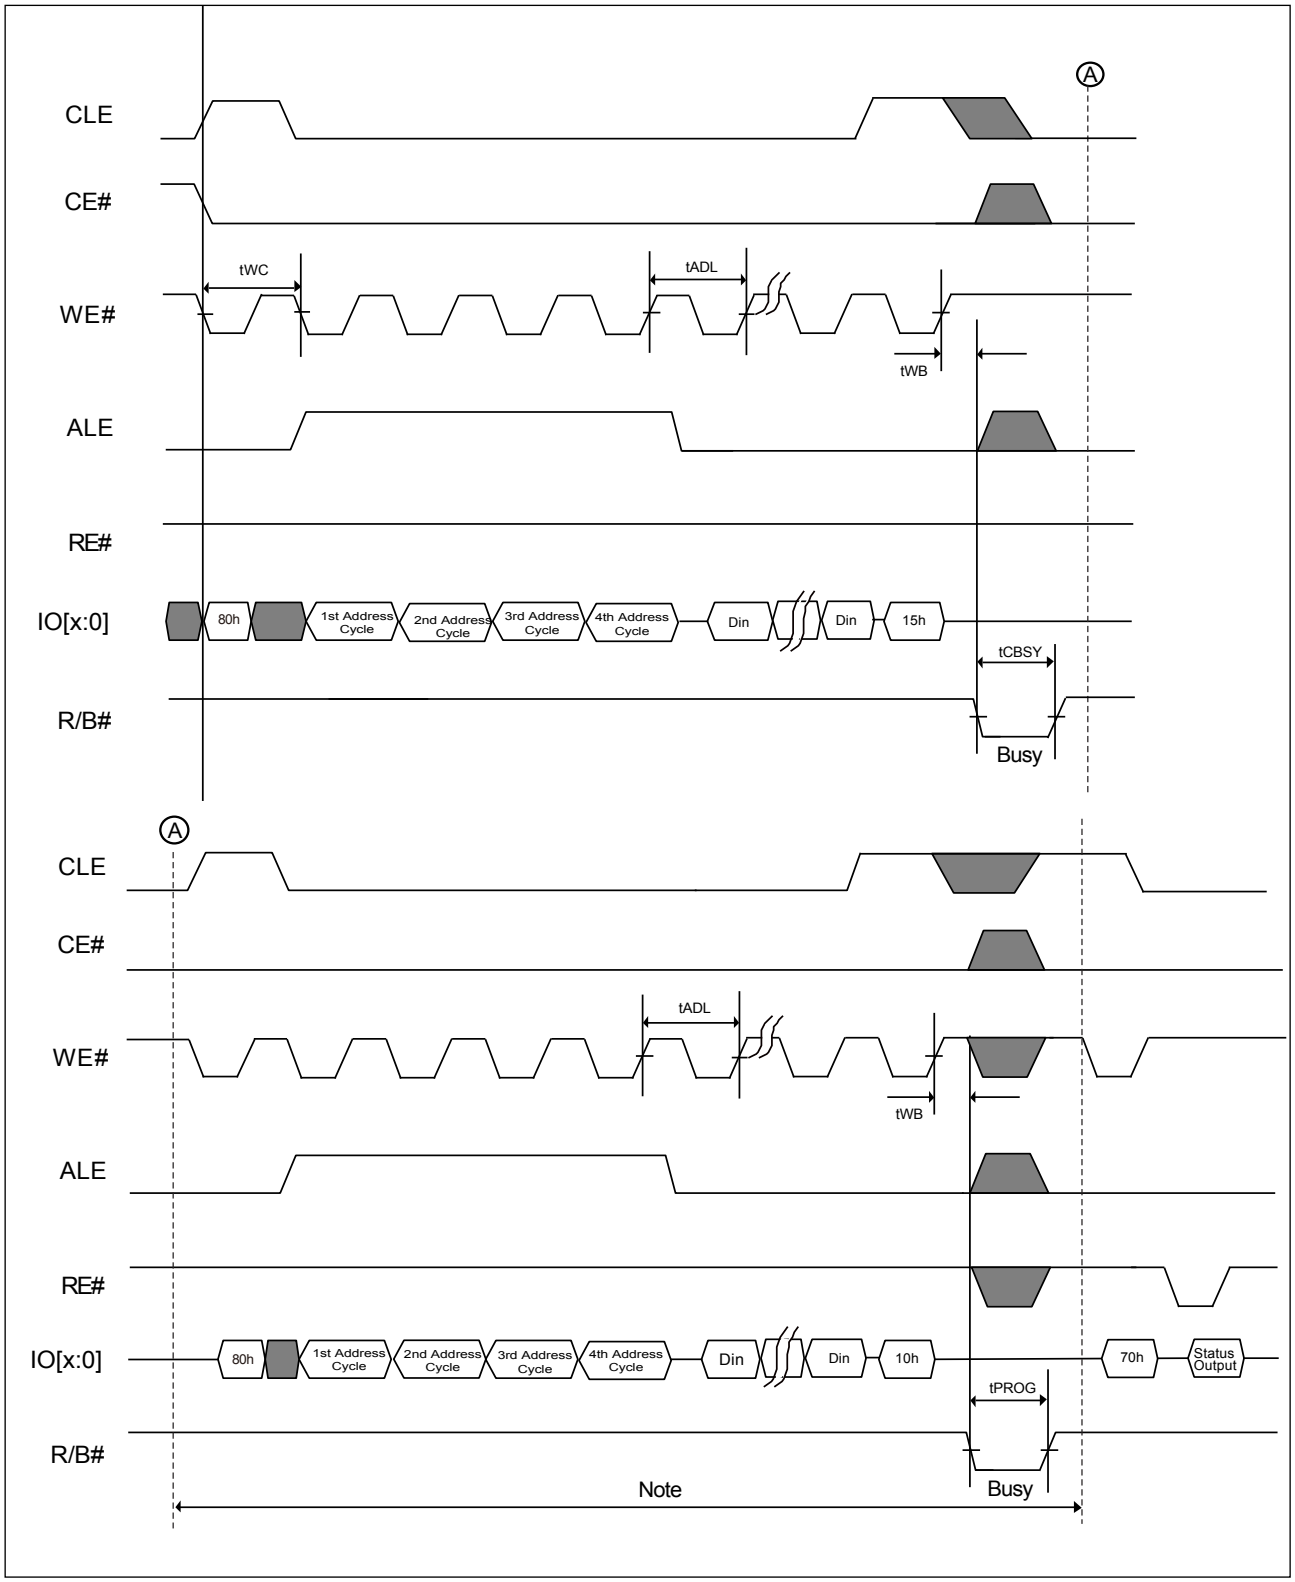

The user can issue another Cache Program Command Sequence after the Cache is ready. The user can always monitor the chip state by Ready/Busy Status Bit (SR[5]). The user can issues either program confirm command (10h) or cache program command (15h) for the last page if the user monitor the chip status by issuing Read Status Command (70h).

However, if the user only monitors the R/B# pin, the user needs to issue the program confirm command (10h) for the last page.

The user can check the Pass/Fail Status through P/F Status Bit (SR[0]) and Cache P/F Status Bit (SR[1]). SR[1] represents Pass/Fail Status of the previous page. SR[1] is updated when SR[6] change from 0 to 1 or Chip is ready. SR[0] shows the Pass/Fail status of the current page. It is updated when SR[5] change from "0" to "1" or the end of the internal programming. For more details, please refer to the related waveforms.

6-7. Block Erase

This device supports a block erase command. This command will erase a block of 64 pages associated with the most significant address bits.

The completion of the erase operation can be detected by R/B# pin or Status register bit (IO6). Recommend to check the status register bit IO0 after the erase operation completes.

During the erasing process, only the read status register command and reset command can be accepted, others are ignored.

6-8. ID Read

The device contains ID codes that identify the device type and the manufacturer. The ID READ command sequence includes one command Byte (90h), one address byte (00h). The Read ID command 90h may provide the manufacturer ID (C2h) of one-byte and device ID (A1h for x8; B1h for x16) of one-byte, also Byte2, Byte3, and Byte4 ID code are followed.

The device support ONFI Parameter Page Read, by sending the ID Read (90h) command and following one byte address (20h), the four-byte data returns the value of 4Fh-4Eh-46h-49h for the ASCII code of "O"-"N"-"F"-"I" to identify the ONFI parameter page.

Table 2. ID Codes Read Out by ID Read Command 90H

ID Code	1Gb, x8, 1.8V	1Gb, x16, 1.8V
Byte0-Manufacturer	C2h	C2h
Byte1: Device ID	A1h	B1h
Byte2	80h	80h
Byte3	15h	55h
Byte4	02h	02h

Note: *For x16, high byte is don't care.*

6-9. Status Read

The MX30UF1G16(18)AC provides a status register that outputs the device status by writing a command code 70h, and then the IO pins output the status at the falling edge of CE# or RE# which occurs last. Even though when multiple flash devices are connecting in system and the R/B#pins are common-wired, the two lines of CE# and RE# may be checked for individual devices status separately.

The status read command 70h will keep the device at the status read mode unless next valid command is issued. The resulting information is outlined in **Table 4** as below.

Table 4. Status Output

Pin	Status	Related Mode	Value	
SR[0]	Chip Status	Page Read, Cache Read, Page Program, Cache Program (Page N), Block Erase	0: Passed	1: Failed
SR[1]	Cache Program Result	Cache Program (Page N-1)	0: Passed	1: Failed
SR[2-4]	Not Used			
SR[5]	Ready / Busy (For P/E/R Controller)	Cache Program/Cache Read operation, other Page Program/Block Erase/Read are same as IO6 (Note 1)	0: Busy	1: Ready
SR[6]	Ready / Busy	Page Program, Block Erase, Cache Program, Read, Cache Read (Note 2)	0: Busy	1: Ready
SR[7]	Write Protect	Page Program, Block Erase, Cache Program, Read	0: Protected	1: Unprotected

Notes:

1. *During the actual programming operation, the SR[5] is "0" value; however, when the internal operation is completed during the cache mode, the SR[5] returns to "1".*
2. *The SR[6] returns to "1" when the internal cache is available to receive new data. The SR[6] value is consistent with the R/B#.*

6-10. Block Protection Status Read

The Block Protection Status Read command (7Ah) may check the protect/un-protect status of blocks. The status output is shown in **Table 5. Block Protection Status Output** and the address cycle is referred to T**able 6-1 & 6-2. Address Cycle Definition of Block.**

Table 5. Block-Protection Status Output

Block-Protection Status	IO[15:3]	IO2(PT#)	IO1(SP#)	IO0(SP)
Block is protected, and device is solid-protected	x	0	0	1
Block is protected, and device is not solid-protected	x	0	1	0
Block is un-protected, and device is solid-protected	x	1	0	1
Block is un-protected, and device is not solid-protected	x	1	1	0

Note: *SP stands for Solid-protected. Once the SP bit sets as 1, the rest of the protection bits (BPx bits, Invert bit, Complementary bit) cannot be changed during the current power cycle.*

Table 6-1. Address Cycle Definition of Block (For x 8)

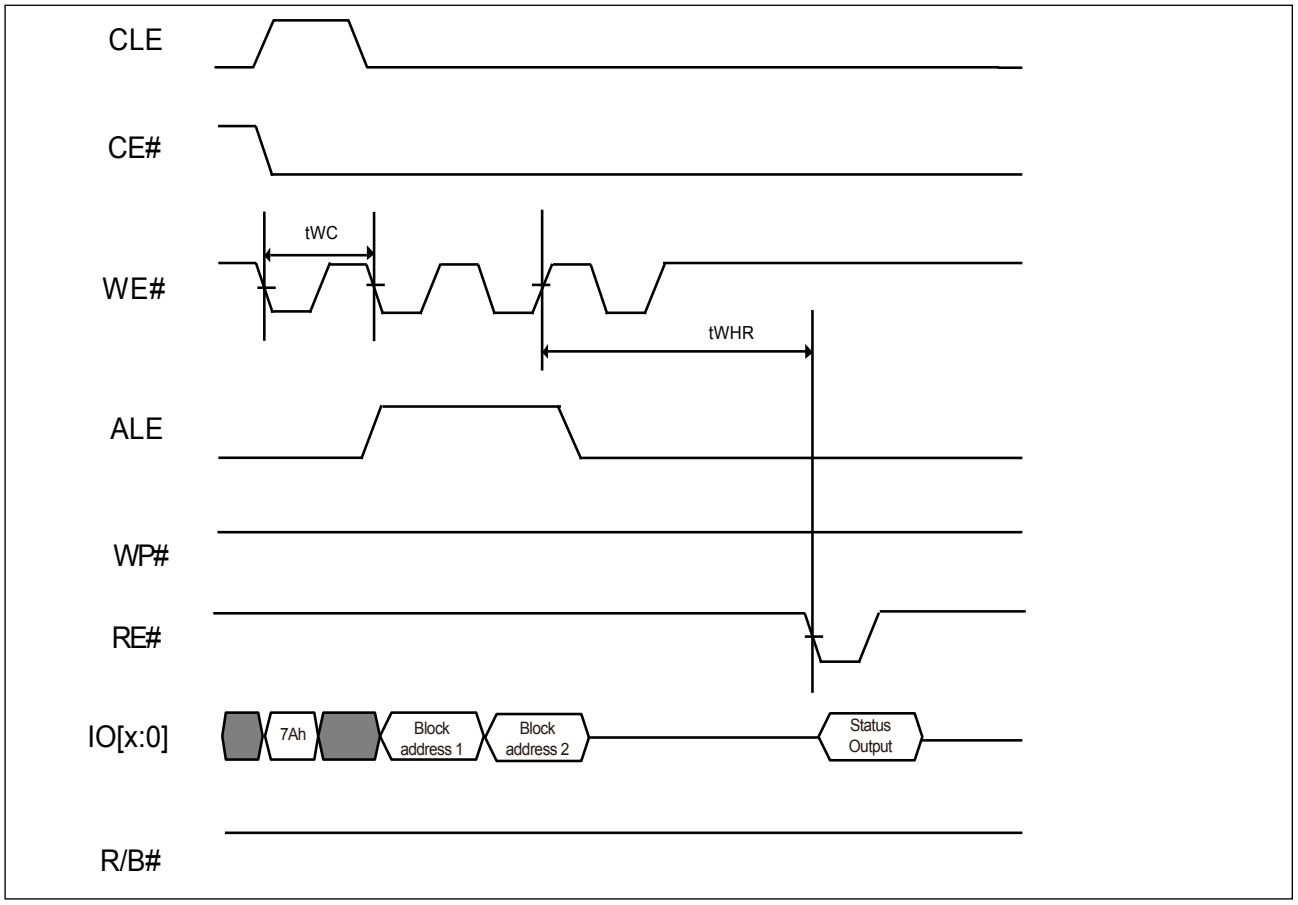

Address Cycle	IO7	IO6	IO5	IO4	IO3	IO2	IO1	IO0
Block Address 1	A19	A18	L	L	L	L	L	L
Block Address 2	A27	A26	A25	A24	A23	A22	A21	A20

Table 6-2. Address Cycle Definition of Block (For x 16)

Address Cycle	IO15-IO8	IO7	IO6	IO5	IO4	IO3	IO2	IO1	IO0
Block Address 1	L	A18	A17	L	L	L	L	L	L
Block Address 2	L	A26	A25	A24	A23	A22	A21	A20	A19

6-11. Reset

The reset command FFh resets the read/program/erase operation and clear the status register to be E0h after chip returns to ready state (when WP# is high). The reset command during the program/erase operation will result in the content of the selected locations(perform programming/erasing) might be partially programmed/ erased.

If the Flash memory has already been set to reset stage with reset command, the additional new reset command is invalid.

6-12. Parameter Page Read (ONFI)

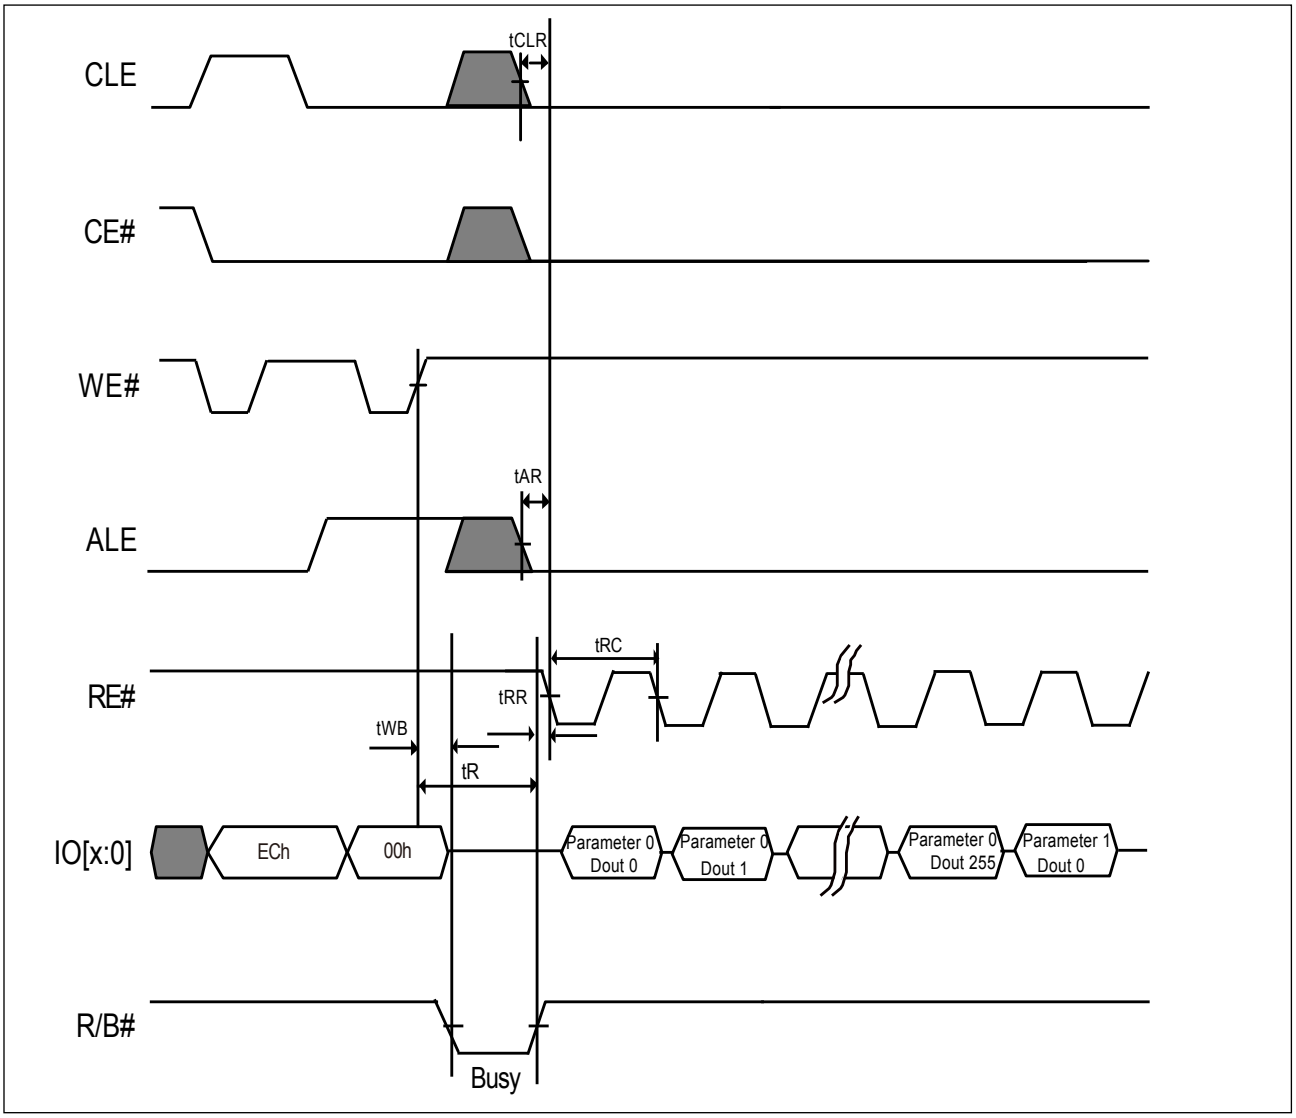

The NAND Flash device support ONFI Parameter Page Read and the parameter can be read out by sending the command of ECh and giving the address 00h. The NAND device information may refer to the table of parameter page(ONFI), there are three copies of 256-byte data and additional redundant parameter pages.

Once sending the ECh command, the NAND device will remain in the Parameter Page Read mode until next valid command is sent.

The Random Data Out command set (05h-E0h) can be used to change the parameter location for the specific parameter data random read out.

The Status Read command (70h) can be used to check the completion with a following read command (00h) to enable the data out.

Vendor Blocks			
Byte#	**Description**		**Data**
164-165	Vendor Specific Revision Number		00h
166-253	Vendor Specific		00h
254-255	Integrity CRC		Set at Test ***(Note)***
Redundant Parameter Pages			
Byte#	**Description**		**Data**
256-511	Value of Bytes 0-255		
512-767	Value of Bytes 0-255		
768+	Additional Redundant Parameter Pages		

Note: *The Integrity CRC (Cycling Redundancy Check) field is used to verify that the contents of the parameters page were transferred correctly to the host. Please refer to ONFI 1.0 specifications for details.*

The CRC shall be calculated using the following 16-bit generator polynomial:

$G(X) = X_{16} + X_{15} + X_2 + 1$

6-13. Unique ID Read (ONFI)

The unique ID is 32-byte and with 16 copies for back-up purpose. After writing the Unique ID read command (EDh) and following the one address byte (00h), the host may read out the unique ID data. The host need to XOR the 1st 16-byte unique data and the 2nd 16-byte complement data to get the result, if the result is FFh, the unique ID data is correct; otherwise, host need to repeat the XOR with the next copy of Unique ID data.

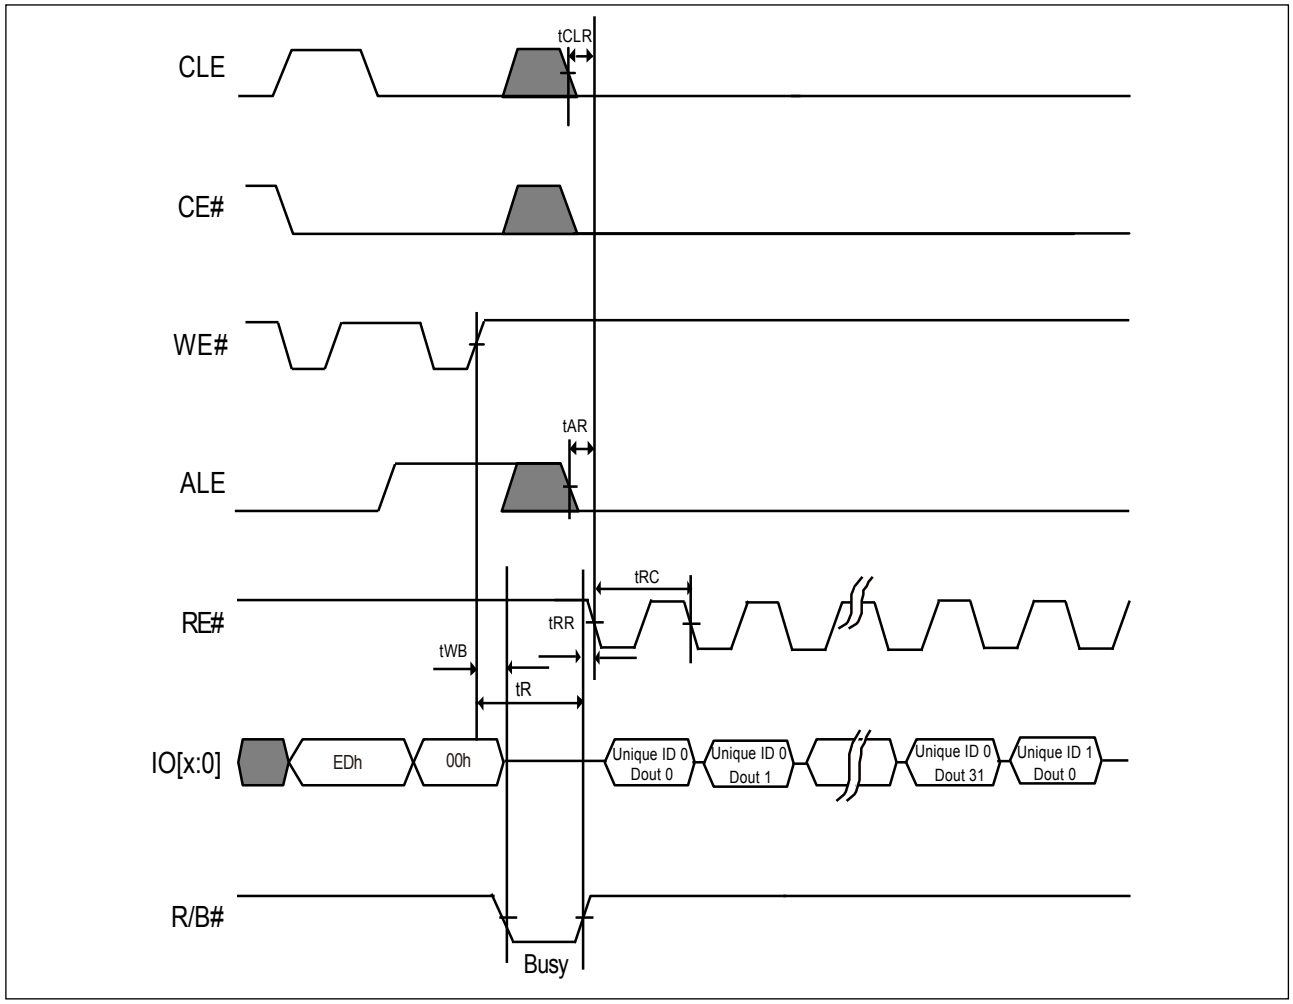

Once sending the EDh command, the NAND device will remain in the Unique ID read mode until next valid command is sent.

To change the data output location, it is recommended to use the Random Data Out command set (05h-E0h).

The Status Read command (70h) can be used to check the completion. To continue the read operation, a following read command (00h) to re-enable the data out is necessary.

6-14. Feature Set Operation (ONFI)

The Feature Set operation is to change the default power-on feature sets by using the Set Feature and Get Feature command and writing the specific parameter data (P1-P4) on the specific feature addresses. The NAND device may remain the current feature set until next power cycle since the feature set data is volatile. However, the reset command (FFh) can not reset the current feature set.

Table 8-1. Definition of Feature Address

Feature Address	Description
00h	Reserved
02h-7Fh	Reserved
80h-8Fh, 91h-9Fh,A1h-FFh	Reserved
90h	Array Operation Mode
A0h	Block Protection Operation

Table 8-2. Sub-Feature Parameter Table of Feature Address - 90h (Array Operation Mode)

Sub Feature Parameter	Definition		IO7	IO6	IO5	IO4	IO3	IO2	IO1	IO0	Values	Note
P1	Array Operation Mode	Normal	Reserved (0)						0	0	0000 0000b	*
		OTP Operation	Reserved (0)				0	0	0	1	0000 0001b	
		OTP Protection	Reserved (0)				0	0	1	1	0000 0011b	
P2			Reserved (0)								0000 0000b	
P3			Reserved (0)								0000 0000b	
P4			Reserved (0)								0000 0000b	

Note: *The value is clear to 00h at power cycle.*

Table 8-3. Sub-Feature Parameter Table of Feature Address - A0h (Block Protection Operation) (Note 1)

Sub Feature Parameter	Definition		IO7	IO6	IO5	IO4	IO3	IO2	IO1	IO0	Values	Note
P1	Block Protection Operation	Default mode	0	0	1	1	1	0	0	0	38h	2
		Protection Bit Setting	0	0	BP2	BP1	BP0	Invert	Complementary	SP	note 3	4
P2			Reserved (0)									
P3			Reserved (0)									
P4			Reserved (0)									

Notes:

1. *If the PT pin is not connected to high, this sub-feature address A0h command is not valid.*
2. *The value is returned to 38h at power cycle.*
3. *The value is defined in the "Table 9. Definition of Protection Bits".*
4. *The SP stands for Solid-Protection. Once the SP bit sets as 1, the rest of protection bits cannot be changed during the current power cycle.*

6-14-1. Set Feature (ONFI)

The Set Feature command is to change the power-on default feature set. After sending the Set Feature command (EFh) and following specific feature and then input the P1-P4 parameter data to change the default power-on feature set. Once sending the EFh command, the NAND device will remain in the Set Feature mode until next valid command is sent.

The Status Read command (70h) may check the completion of the Set Feature.

Figure 26. AC Waveforms for Set Feature (ONFI) Operation

Note: *For x16, IO[15:8] should be 00h.*

Web:www.manduic.com
Tel:150-1290-5940
Email:sales@manduic.com
Downloaded from Arrow.com.

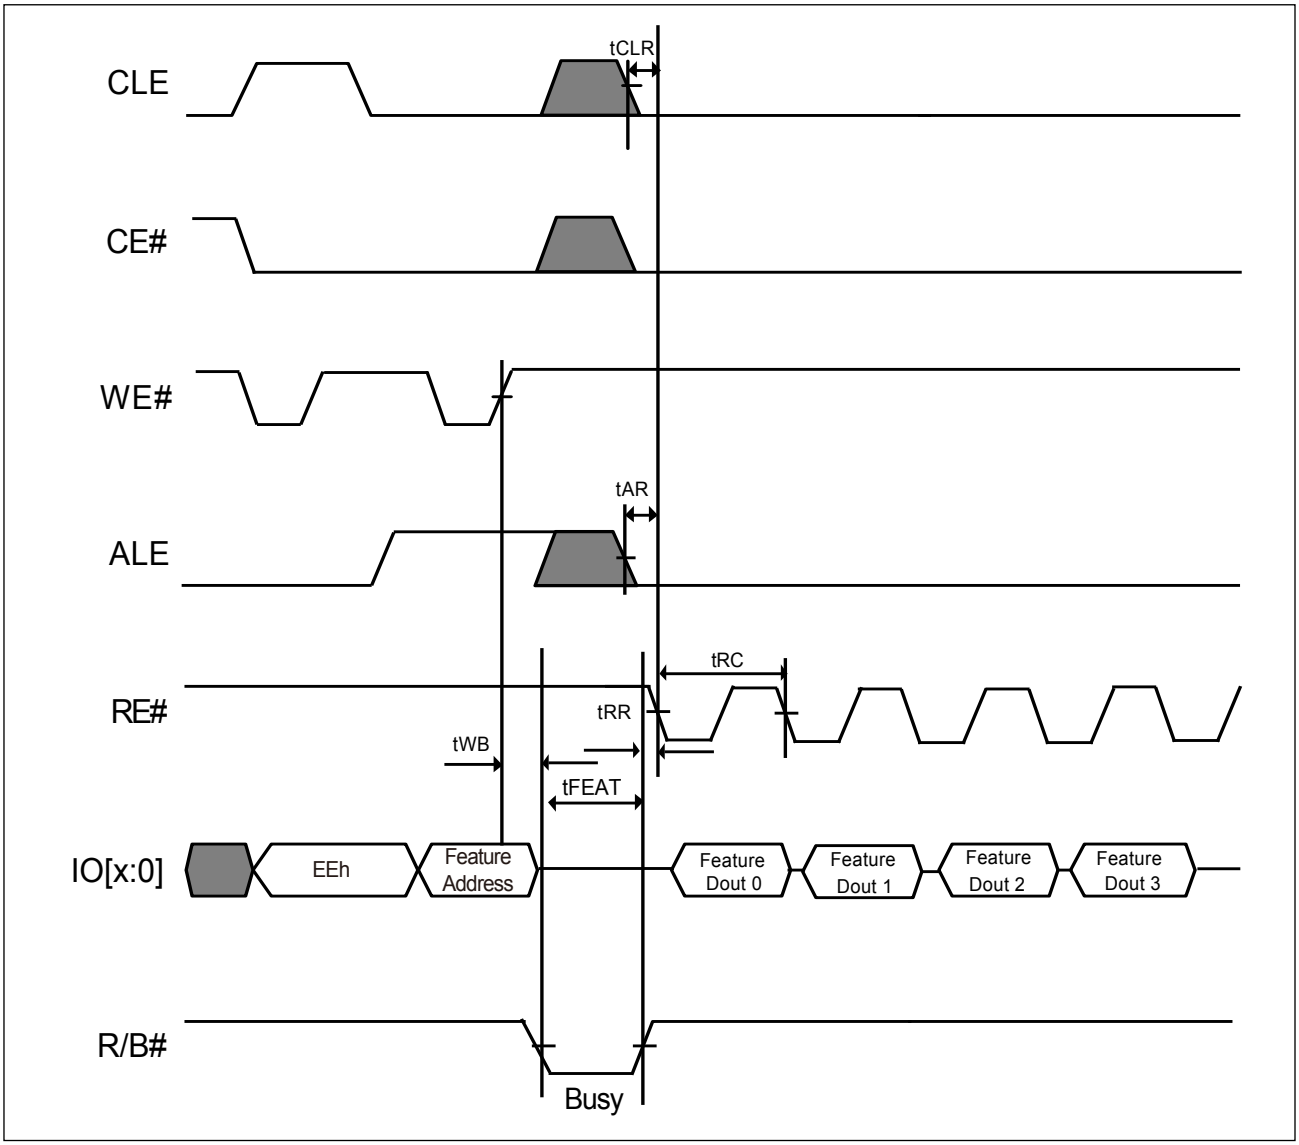

6-14-2. Get Feature (ONFI)

The Get Feature command is to read sub-feature parameter. After sending the Get Feature command (EEh) and following specific feature, the host may read out the P1-P4 sub- feature parameter data. Once sending the EEh command, the NAND device will remain in the Get Feature mode until next valid command is sent.

The Status Read command (70h) can be used to check the completion. To continue the read operation, a following read command (00h) to re-enable the data out is necessary.

Please refer to the following waveform of **Get Feature Operation** for details.

6-14-3. Secure OTP (One-Time-Programmable) Feature

There is an OTP area which has thirty full pages (30 x 2,112-byte) guarantee to be good for system device serial number storage or other fixed code storage. The OTP area is a non-erasable and one-time-programmable area, which is default to “1” and allows whole page or partial page program to be “0”, once the OTP protection mode is set, the OTP area becomes read-only and cannot be programmed again.

The OTP operation is operated by the Set Feature/ Get Feature operation to access the OTP operation mode and OTP protection mode.

To check the NAND device is ready or busy in the OTP operation mode, either checking the R/B# or writing the Status Read command (70h) may collect the status.

To exit the OTP operation or protect mode, it can be done by writing 00h to P1 at feature address 90h.

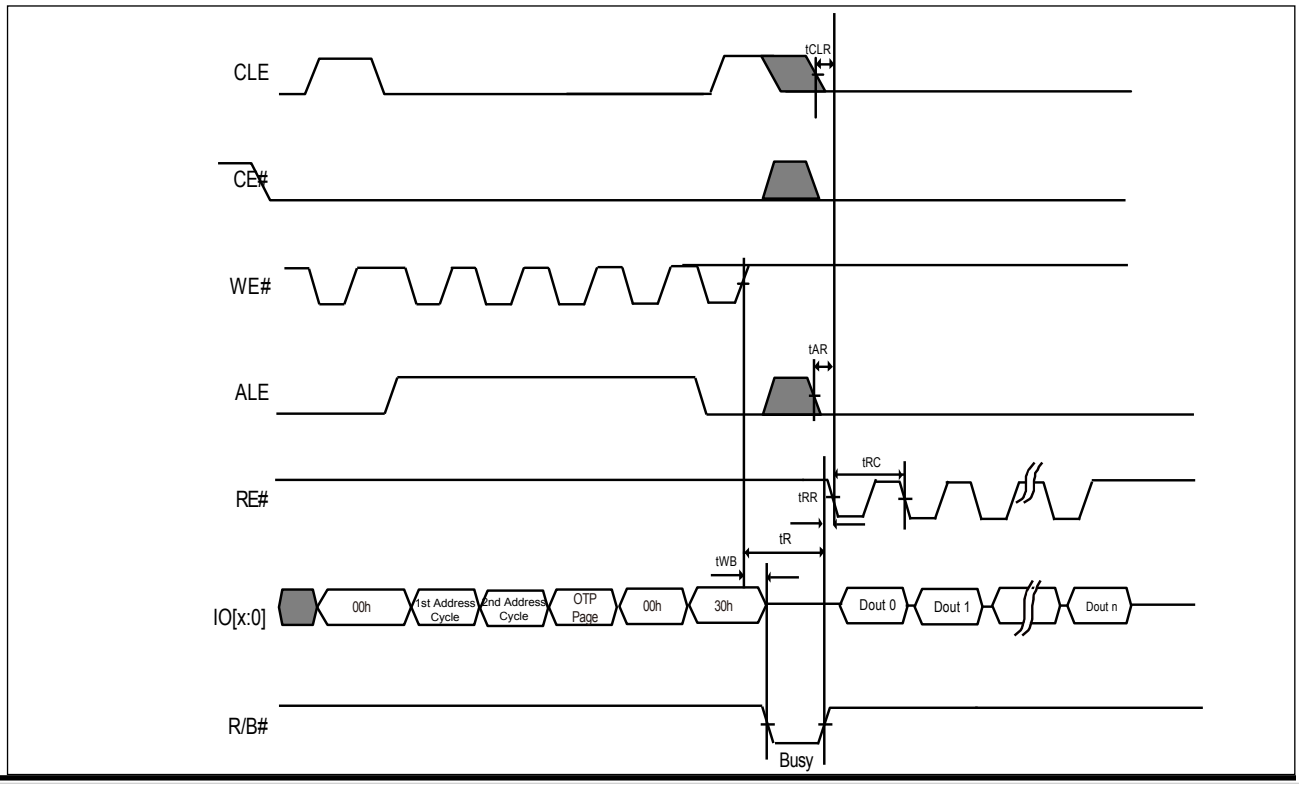

OTP Read/Program Operation

To enter the OTP operation mode, it is by using the Set Feature command (EFh) and followed by the feature address (90h) and then input the 01h to P1 and 00h to P2-P4 of sub-Feature Parameter data(please refer to the sub-Feature Parameter table). After enter the OTP operation mode, the normal Read command (00h-30h) or Page program(80h-10h) command can be used to read the OTP area or program it. The address of OTP is located on the 02h-1Fh of page address.

Besides the normal Read command, the Random Data Output command (05h-E0h) can be used for read OTP data. However, the Cache Read command is not supported in the OTP area.

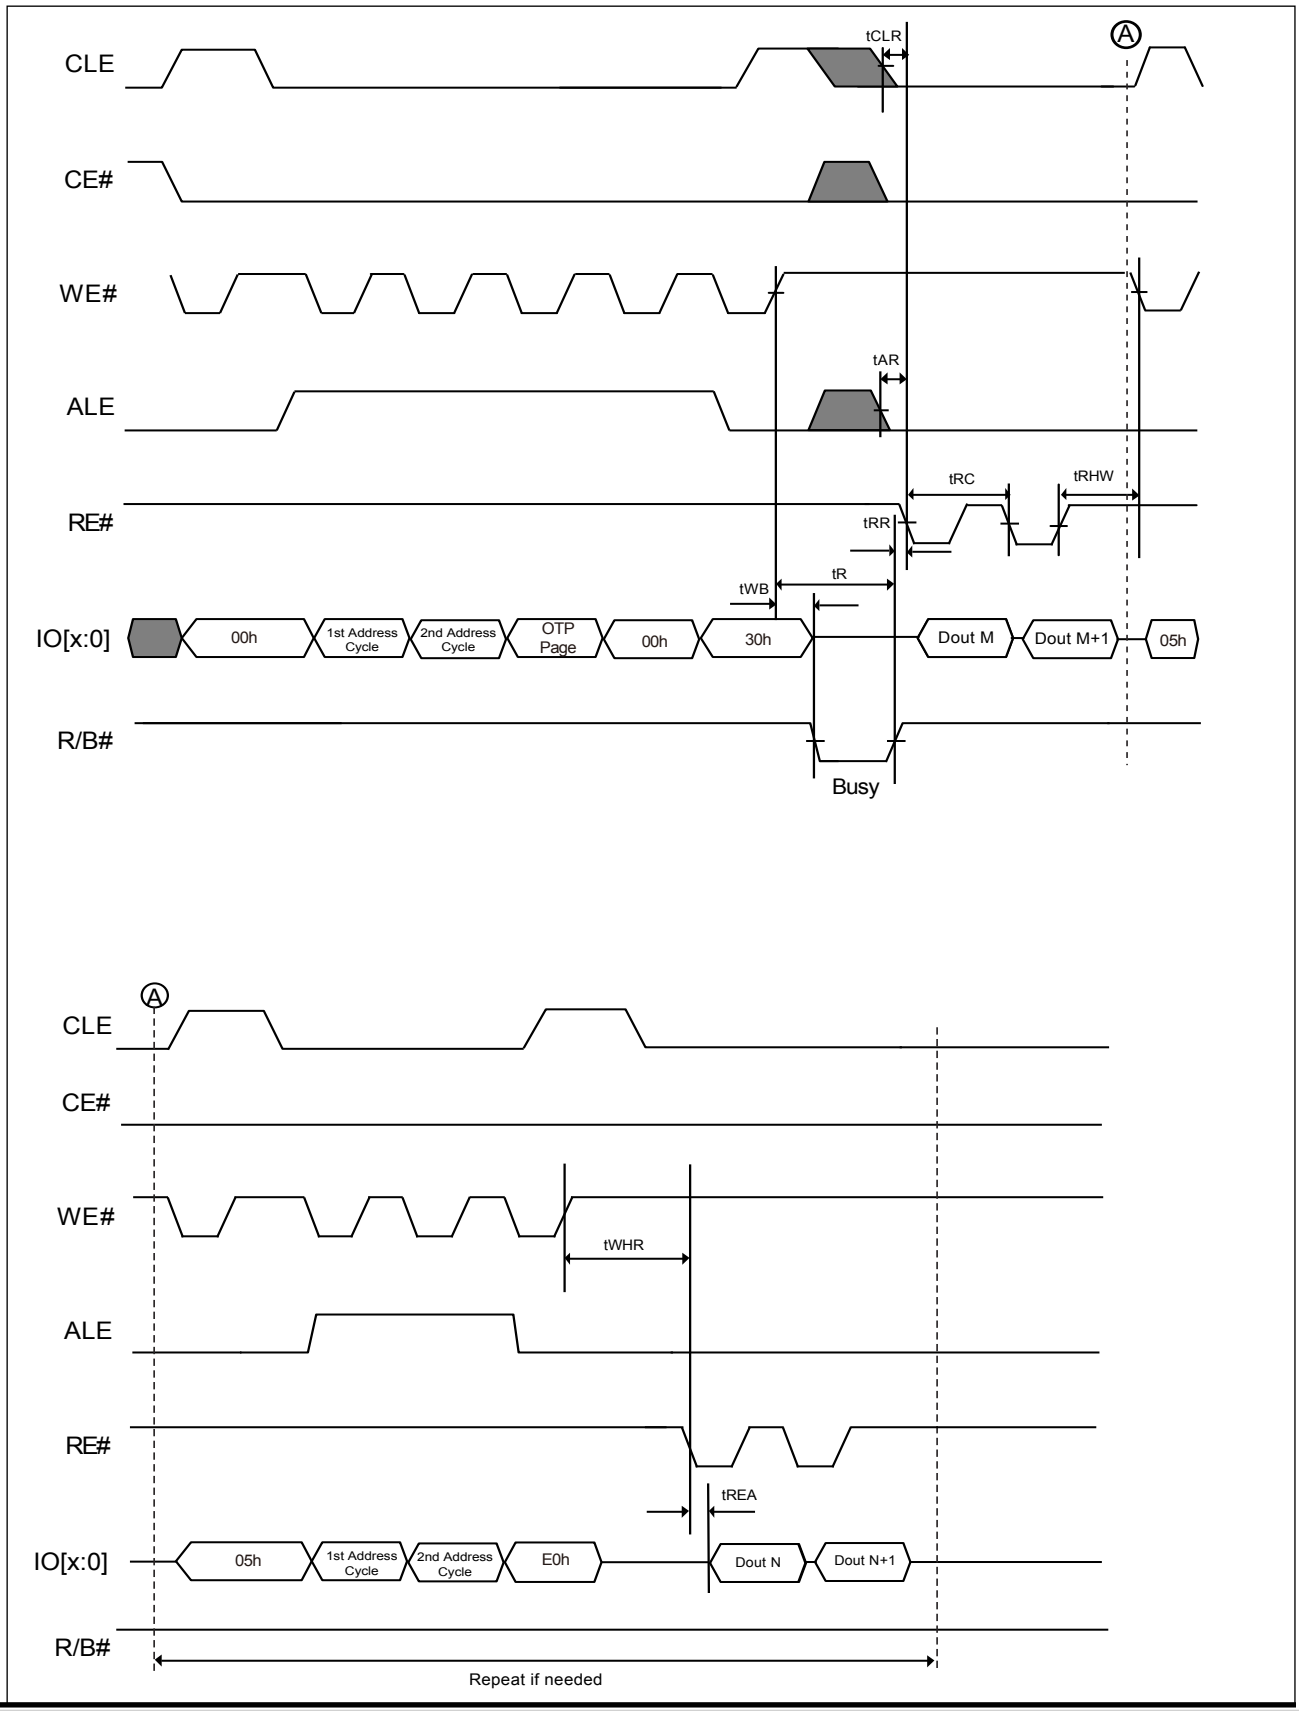

Besides the normal page program command, the Random Data Input command (85h) allows multi-data load in non-sequential address. After data load is completed, a program confirm command (10h) is issued to start the page program operation. The number of partial-page OTP program is 8 per each OTP page.

OTP Protection Operation

To prevent the further OTP data to be changed, the OTP protection mode operation is necessary. To enter the OTP protection mode, it can be done by using the Set Feature command (EFh) and followed by the feature address (90h) and then input the 03h to P1 and 00h to P2-P4 of sub-Feature Parameter data (please refer to the sub-Feature Parameter table). And then the normal page program command (80h-10h) with the address 00h before the 10h command is required.

The OTP Protection mode is operated by the whole OTP area instead of individual OTP page. Once the OTP protection mode is set, the OTP area cannot be programmed or unprotected again.

6-14-4. Block Protection

The block protect operation can protect the whole chip or selected blocks from erasing or programming. Through the PT pin at power-on stage, it decides the block protection operation is enabled or disabled. At power-on, if the PT pin is connected to high, the block protection operation is enabled, all the blocks are default to be protected from programming/erasing even the WP# is disabled. If the PT pin is low, block protection operation is disabled. Please refer to the **Figure 33. PT Pin and Block Protection Mode Operation**.

When program or erase attempt at a protected block is happened, the R/B# keeps low for the time of tPBSY, and the Status Read command (70h) may get the 60h result.

There are Temporary Protection/un-Protection and Solid Protection features as below description.

Temporary Protection/un-Protection

At power-on, if the PT pin is connected to high, all the blocks are default to be protected for the BPx protection bits are all "1". The Set feature command with feature address A0h followed by the destined protection bits data is necessary to un-protect those selected blocks before those selected blocks to be updated. The WP# pin needs to connect to high before writing the Set Feature command for the block protection operation. After the selected blocks are un-protected, those un-protected blocks can be protected again by Block Protection procedure if required.

Solid Protection

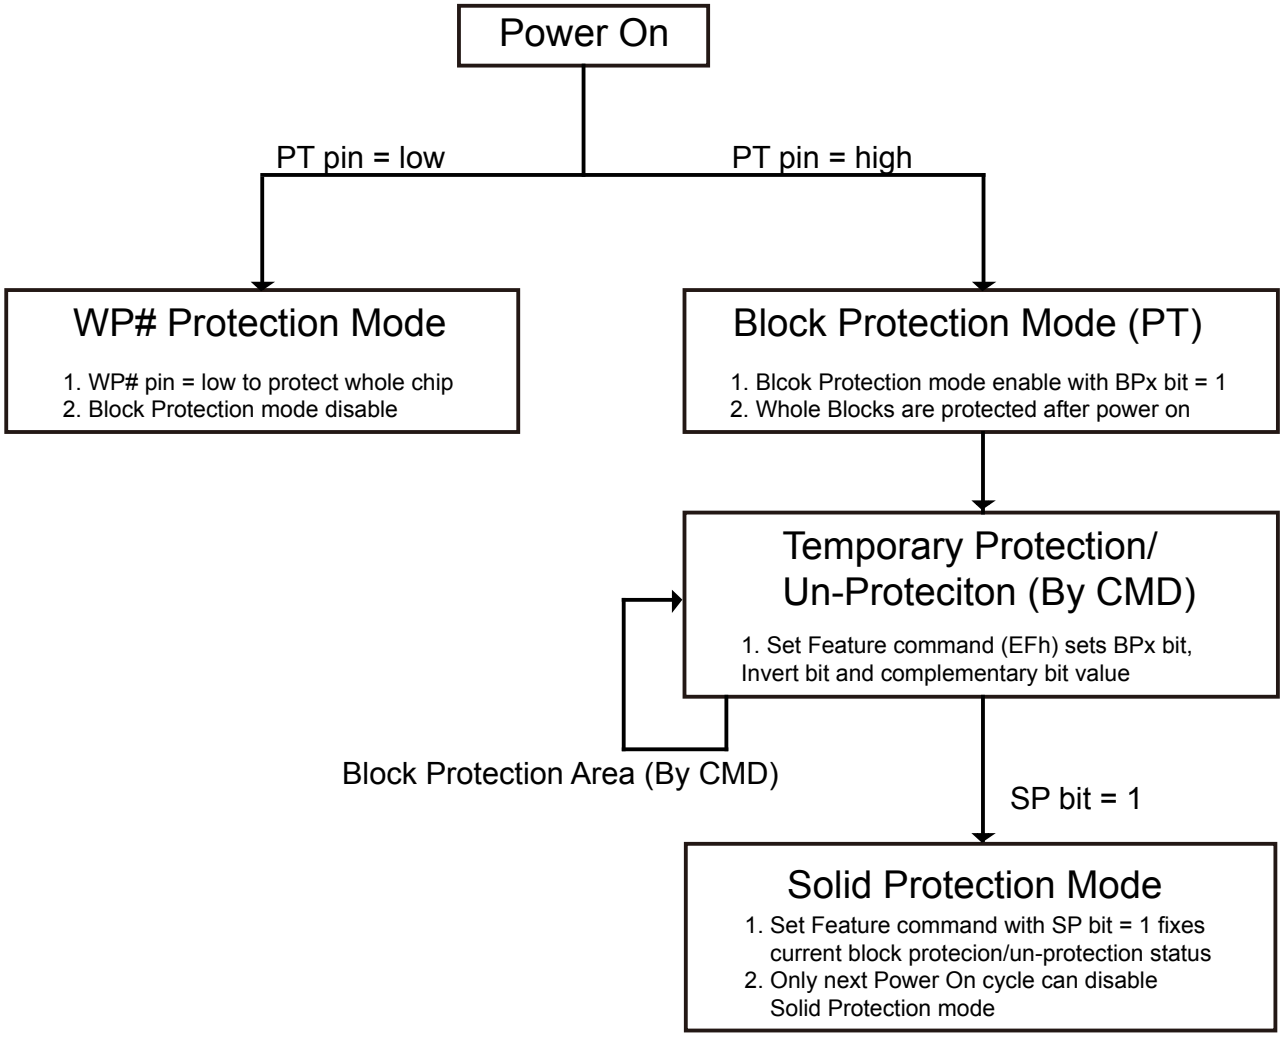

The "solid-protection" feature can be set by writing the Set Feature command with address A0h and the "SP" solid-protection bit as "1", after that, the selected block is solid-protected and cannot be up-protected until next power cycle.

Table 9. Definition of Protection Bits

BP2	BP1	BP0	Invert	Complementary	Protection Area
0	0	0	x	x	all unlocked
0	0	1	0	0	upper 1/64 locked
0	1	0	0	0	upper 1/32 locked

7. PARAMETERS

7-1. ABSOLUTE MAXIMUM RATINGS

Temperature under Bias	-50°C to +125°C
Storage temperature	-65°C to +150°C
All input voltages with respect to ground (Note 2)	-0.6V to 2.4V
VCC supply voltage with respect to ground (Note 2)	-0.6V to 2.4V
ESD protection	>2000V

Notes:

1. *The reliability of device may be impaired by exposing to extreme maximum rating conditions for long range of time.*
2. *Permanent damage may be caused by the stresses higher than the "Absolute Maximum Ratings" listed.*
3. *During voltage transitions, all pins may overshoot to VCC +1.0V or -1.0V for period up to 20ns. See the two waveforms as below.*

Table 10. Operating Range

Temperature	VCC	Tolerance
-40°C to +85°C	+1.8V	1.7 ~ 1.95V

Table 11. DC Characteristics

Symbol	Parameter	Test Conditions	Min.	Typical	Max.	Unit	Notes
VIL	Input low level		-0.3		0.2VCC	V	
VIH	Input high level		0.8VCC		VCC + 0.3	V	
VOL	Outout low voltage	IOL= 100uA, VCC= VCC Min.			0.1	V	1
VOH	Outout high voltage	IOH= -100uA, VCC= VCC Min.	VCC-0.1V			V	1
ISB1	VCC standby current (CMOS)	CE# = VCC -0.2V, WP# = 0/VCC		10	50	uA	
ISB2	VCC standby current (TTL)	CE# = VIH Min., WP# = 0/VCC			1	mA	
IST	Staggered power-up current	Rise time = 1ms, Line capacitance = 0.1uF		20	30	mA	2
ICC1	VCC active current (Sequential Read)	tRC Min., CE# = VIL, IOUT= 0mA		23	30	mA	3
ICC2	VCC active current (Program)			23	30	mA	3
ICC3	VCC active current (Erase)			15	30	mA	3
ILI	Input leakage current	VIN= 0 to VCC Max.			+/- 10	uA	
ILO	Output leakage current	VOUT= 0 to VCC Max.			+/- 10	uA	
ILO (R/B#)	Output current of R/B# pin	VOL=0.2V	3	4		mA	1

Notes:

1. The test can be initiated after VCC goes VCC (min) and performed under the condition of 1mS interval.

2. It is necessary to set ILO(R/B#) to be relaxed if the strength of R/B# pull-down is not set to full. And the VOL/VOH will be relaxed if the strength of I/O drive is not full.

8. OPERATION MODES: LOGIC AND COMMAND TABLES

Address input, command input and data input/output are managed by the CLE, ALE, CE#, WE#, RE# and WP# signals, as shown in **Table 16. Logic Table** below.

Program, Erase, Read and Reset are four major operations modes controlled by command sets, please refer to **Table 17**.

Table 16. Logic Table

Mode	CE#	RE#	WE#	CLE	ALE	WP#
Address Input (Read Mode)	L	H	↑	L	H	X
Address Input (Write Mode)	L	H	↑	L	H	H
Command Input (Read Mode)	L	H	↑	H	L	X
Command Input (Write Mode)	L	H	↑	H	L	H
Data Input	L	H	↑	L	L	H
Data Output	L	↓	H	L	L	X
During Read (Busy)	X	H	H	L	L	X
During Programming (Busy)	X	X	X	X	X	H
During Erasing (Busy)	X	X	X	X	X	H
Program/Erase Inhibit	X	X	X	X	X	L
Stand-by	H	X	X	X	X	0V/VCC

Notes:

1. *H = VIH; L = VIL; X = VIH or VIL*
2. *WP# should be biased to CMOS high or CMOS low for stand-by.*

Downloaded from Arrow.com.

Table 17. HEX Command Table

	First Cycle	Second Cycle	Acceptable While Busy
Read Mode	00H	30H	
Random Data Input	85H	-	
Random Data Output	05H	E0H	
Cache Read Random	00H	31H	
Cache Read Sequential	31H	-	
Cache Read End	3FH	-	
ID Read	90H	-	
Parameter Page Read (ONFI)	ECH	-	
Unique ID Read (ONFI)	EDH	-	
Set Feature (ONFI)	EFH	-	
Get Feature (ONFI)	EEH	-	
Reset	FFH	-	V
Page Program	80H	10H	
Cache Program	80H	15H	
Block Erase	60H	D0H	
Status Read	70H	-	V
Block Protection Status Read	7AH	-	

Caution: *None of the undefined command inputs can be accepted except for the command set in the above table.*

Note: *The IO15-IO8 should be "0" while writing command code for the x16 NAND device.*

8-1. R/B#: Termination for The Ready/Busy# Pin (R/B#)

The R/B# is an open-drain output pin and a pull-up resistor is necessary to add on the R/B# pin. The R/B# outputs the ready/busy status of read/program/ erase operation of the device. When the R/B# is at low, the device is busy for read or program or erase operation. When the R/B# is at high, the read/program/erase operation is finished.

Rp Value Guidence

The rise time of the R/B# signal depends on the combination of Rp and capacitive loading of the R/B# circuit. It is approximately two times constants (Tc) between the 10% and 90% points on the R/B# waveform.

$$T_C = R \times C$$

Where $R = R_p$ (Resistance of pull-up resistor), and $C = C_L$ (Total capacitive load)

The fall time of the R/B# signal majorly depends on the output impedance of the R/B# signal and the total load capacitance.

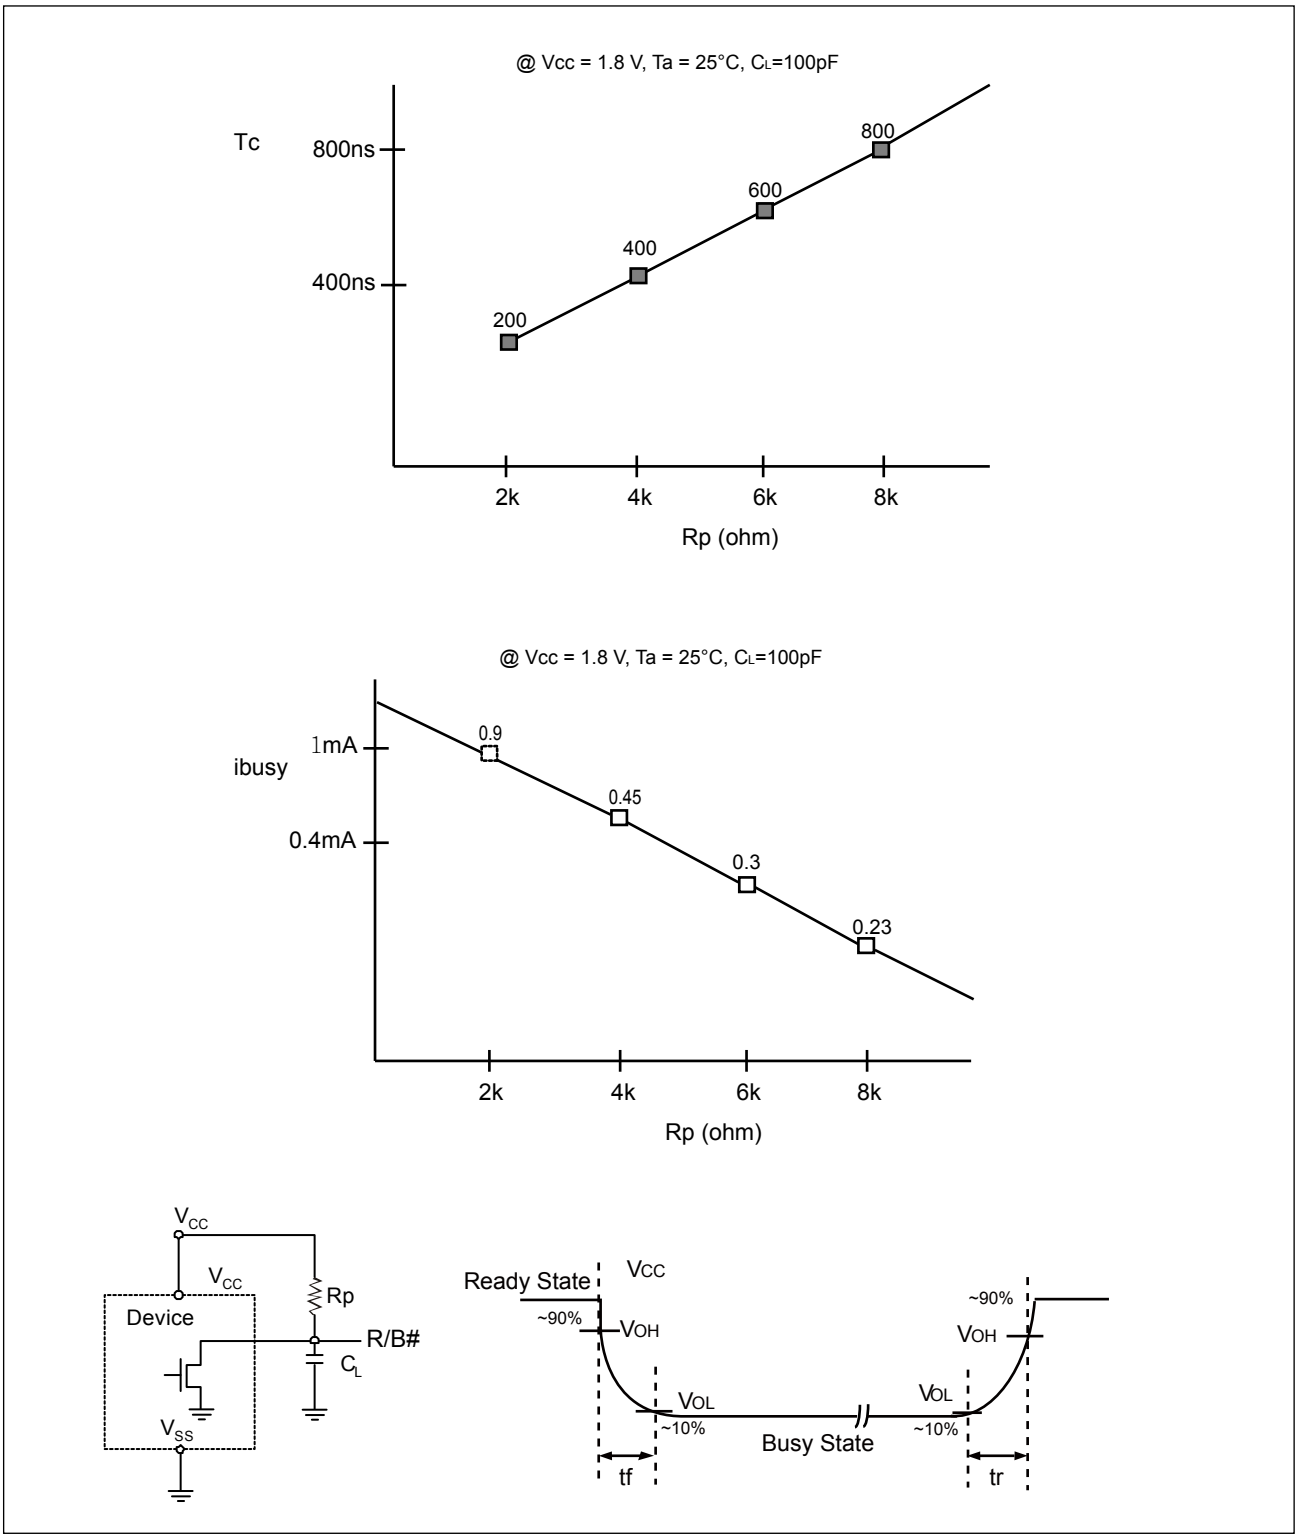

$$Rp\ (Min.) = \frac{Vcc\ (Max.) - VOL\ (Max.)}{I_{OL} + \Sigma I_L}$$

Notes:

1. *Considering of the variation of device-by-device, the above data is for reference to decide the resistor value.*
2. *Rp maximum value depends on the maximum permissible limit of tr.*
3. *IL is the total sum of the input currents of all devices tied to the R/B pin.*

Downloaded from Arrow.com.

8-2. Power On/Off Sequence

After the Chip reaches the power on level (Vth = Vcc min.), the internal power on reset sequence will be triggered. During the internal power on reset period, no any external command is accepted. There are two ways to identify the termination of the internal power on reset sequence. Please refer to **Figure 37. Power On/Off Sequence**.

- R/B# pin
- Wait 1 ms

During the power on and power off sequence, it is recommended to keep the WP# = Low for internal data protection.

8-2-1. WP# Signal

WP# going Low can cause program and erase operations automatically reset.

The enabling & disabling of the both operations are as below:

Figure 38-1. Enable Programming of WP# Signal

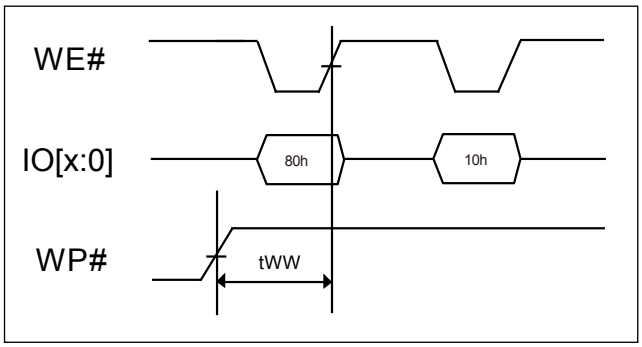

Figure 38-2. Disable Programming of WP# Signal

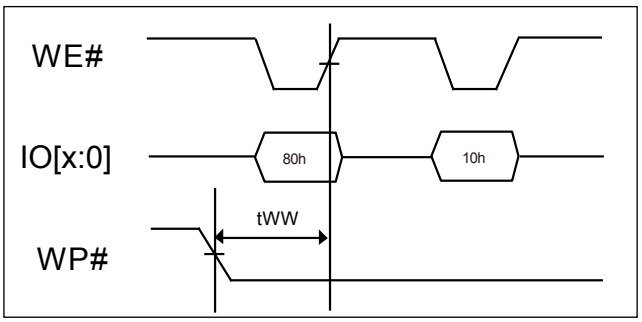

Figure 38-3. Enable Erasing of WP# Signal

9. SOFTWARE ALGORITHM

9-1. Invalid Blocks (Bad Blocks)

The bad blocks are included in the device while it gets shipped. During the time of using the device, the additional bad blocks might be increasing; therefore, it is recommended to check the bad block marks and avoid using the bad blocks. Furthermore, please read out the bad block information before any erase operation since it may be cleared by any erase operation.

Figure 39. Bad Blocks

While the device is shipped, the value of all data bytes of the good blocks are FFh. The 1st byte of the 1st and 2nd page in the spare area for bad block will be 00h for x8; and 0000h for x16. The erase operation at the bad blocks is not recommended.

After the device is installed in the system, the bad block checking is recommended. The figure shows the brief test flow by the system software managing the bad blocks while the bad blocks were found. When a block gets damaged, it should not be used any more.

Due to the blocks are isolated from bit-line by the selected gate, the performance of good blocks will not be impacted by bad ones.

Table 18. Valid Blocks

	Density	Min.	Typ.	Max.	Unit	Remark
Valid (Good) Block Number	1Gb	1004		1024	Block	Block 0 is guaranteed to be good.

深圳市满度科技有限公司
Web:www.manduic.com
Tel:150-1290-5940
Email:sales@manduic.com
Downloaded from Arrow.com.

9-2. Bad Block Test Flow

Although the initial bad blocks are marked by the flash vendor, they could be inadvertently erased and destroyed by a user that does not pay attention to them. To prevent this from occurring, it is necessary to always know where any bad blocks are located. Continually checking for bad block markers during normal use would be very time consuming, so it is highly recommended to initially locate all bad blocks and build a bad block table and reference it during normal NAND flash use. This will prevent having the initial bad block markers erased by an unexpected program or erase operation. Failure to keep track of bad blocks can be fatal for the application. For example, if boot code is programmed into a bad block, a boot up failure may occur. The following section shows the recommended flow for creating a bad block table.

Figure 40. Bad Block Test Flow

Note 1. *Read 00h check is at the 1st bytes of the 1st and 2nd pages of the block spare area*

9-3. Failure Phenomena for Read/Program/Erase Operations

The device may fail during a Read, Program or Erase operation. The following possible failure modes should be considered when implementing a highly reliable system:

Table 19. Failure Modes

Failure Mode	Detection and Countermeasure	Sequence
Erase Failure	Status Read after Erase	Block Replacement
Programming Failure	Status Read after Program	Block Replacement
Read Failure	Read Failure	ECC

深圳市满度科技有限公司
Web:www.manduic.com
Tel:150-1290-5940
Email:sales@manduic.com
Downloaded from Arrow.com.

9-4. Program

It is feasible to reprogram the data into another page (Page B) when an error occurred in Page A by loading from an external buffer. Then create a bad block table or by using another appropriate scheme to prevent further system accesses to Page A.

Figure 41. Failure Modes

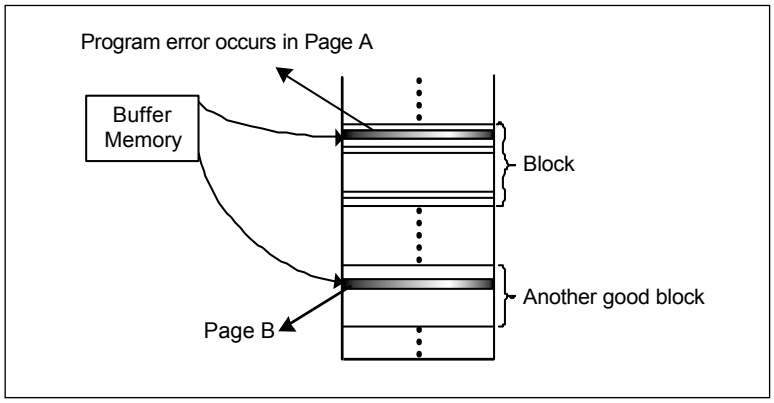

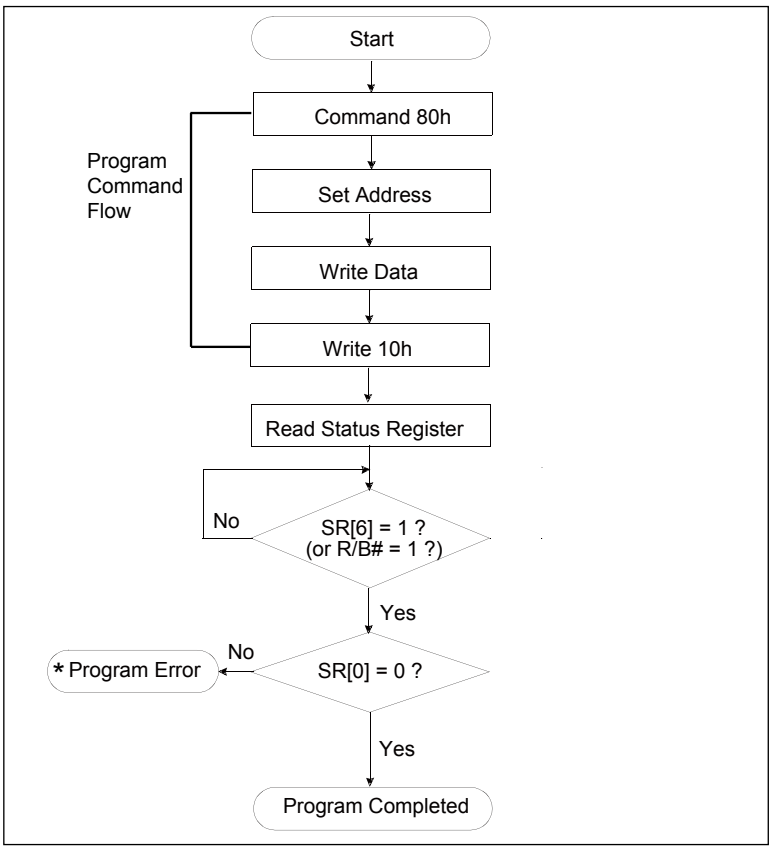

Figure 42. Program Flow Chart

9-5. Erase

To prevent future accesses to this bad block, it is feasible to create a table within the system or by using another appropriate scheme when an error occurs in an Erase operation.

11. REVISION HISTORY

Rev. No.	Descriptions		Page	Date
1.0	1. Removed "Advanced Information" Title	ALL	JAN/08/2015	
	2. Modified Pad Location for 48-ball VFBGA (x8)	P9		
	3. Added a note to Figure 15-2. AC Waveforms for Sequence of Cache Program		P31	
	4. Added Figure 32. PT pin and Block Protection Mode Operation		P54	
	5. Corrected the Max. value of tRHZ in AC Table.	P58		
	6. Revised the bad block mark from non-FFh to 00h, and non-FFFFh to 0000h also revised the page of bad block mark from 1st or 2nd page to 1st and 2nd page		P65,66	
1.1	1. Corrected tALS timing waveform as ALE high till WE# high and tWB timing waveform as WE#high to busy		P26,54	MAR/06/2015
	2. Supplement the missing VFBGA package information		P5, 11-12	
1.2	1. Modified Ordering Information: (1) "-" in "Part Name Descrition" (2.) Additional statement		P7	MAY/02/2016
	2. Corrected the BGA ball-out from "NC" as "VCC1"/"VSS1" to align the ONFI compatibility		P9-10	
	3. Added "Block Protection status read" section		P40,41	
	4. Corrected the value of Feature address 90h		P49	
	5. Added overshoot/undershoot waveforms		P59	
	6. Added the tRST=5us for the device reset time from idle		P62	
	7. Removed redundant Note No. of "Block Protection Status Read" item		P64	
	8. Modification of the power-on/off sequence: supplement the CE# signal, supplement the WE# single waveform with WE#=0 without toggle during the power-on period.		P67
